ABSTRACT

This collection presents papers pertaining to the wide area of educational multimedia/hypermedia and telecommunications. The conference serves as a forum for the dissemination of information on the research, development, and applications in all areas of multimedia/hypermedia and telecommunications in education across all disciplines and levels. The papers cover a range of topics, including specific uses of several different technologies in distance and on-site education; design and implementation; and program and software evaluation. These proceedings contain 178 full papers, reports of 6 panel discussions, 149 short papers, and reports of 50 posters and demonstrations. (AEF)

PREFACE

Welcome to ED-MEDIA/ED-TELECOM 97 in beautiful Calgary, Alberta, CANADA. It is fitting that this tenth in a series of research and development conferences is being held in the same city that hosted the first meeting, the International Conference on Computers and Learning (ICCAL) in 1987. Over the last decade, thanks largely to the efforts of scores of volunteers, ED-MEDIA/ED-TELECOM has become one of the top events of its kind anywhere in the world. An annual event since 1993 when the conference became associated with the Association for the Advancement of Computing in Education (AACE), ED-MEDIA/ED-TELECOM retains many valued aspects of the earlier conferences, most importantly the truly international nature of its participants. At the same time, the conference has grown in sophistication and scope, and we hope that you will find that this year's version lives up both to your memories and your expectations.

In areas as heavily invested in innovation as educational multimedia, hypermedia, and telecommunications, some might question the meaning and value of holding face-to-face conferences for which presentations must be submitted and prepared months in advance. After all, changes in the technologies we employ occur at a faster and faster pace, and last month's cutting-edge news is this month's dull topic. However, most of us recognize that as conference participants we are not so much interested in technologies as ideas. New ideas are often shared, critiqued, and reshaped through personal dialogue and group discussion. Further, we recognize that many of the most important exchanges that take place at professional meetings occur away from formal sessions. Collegial introductions at social events as well as chance meetings in the hall where you make new friends and catch up with old ones, these and many other human interactions are often the most valued and long-remembered aspects of any conference. Although the global "infocasm" described by futurists suggests otherwise, we predict that the basic human need to interact face-to-face will last far into the 21st Century.

As co-chairs of the Program Committee (PC), we have endeavored to increase the quality of the papers, tutorials, workshops, posters, demonstrations, panels, showcases and other events at this year's conference. We could not have done this without the hard work of the PC members listed on the following pages. Representing nearly twenty different countries, these individuals reviewed more proposals than ever before. The papers in this volume and on the accompanying CD-ROM survived several rounds of demanding analysis, critique, and selection, as did the other types of sessions. In addition, the counsel of the Steering Committee members was invaluable, especially in terms of selecting the keynote and invited speakers. Gratitude also goes to the AACE team, most notably Executive Director Gary Marks. Finally, we acknowledge the many and varied efforts of the Local Executive Committee in Calgary, co-chaired by Brian Gaines and Douglas Norrie, of the University of Calgary, our host institution. Thank you one and all.

A year of preparation will soon be over, and ED-MEDIA/ED-TELECOM 97 will be a memory. It is our hope that this memory will be refreshed each time you open this volume or access the conference CD-ROM, seeking information and inspiration for your future work. Further evidence of that living memory will be your continued participation in this event. To that end, we look forward to seeing you again next year at ED-MEDIA/ED-TELECOM 98 in Freiburg, Germany.

The Effects of Structure on Hypertext Design

Abstract[1]

This paper examines the effects of structure on the effectiveness of a relatively large hypertext system. CS 383 consists of 300 pages of course hypertext with 178 cross references, 678 terms with pop-up definitions, and 600 terms that students can search on. Two hypertext systems based on this course material and consisting of the same content were compared. The first system was the originally developed system and its structure was based on the course schedule. The second system was based on an object decomposition of the same material. Using a sample population of thirty-two students, the two systems were compared in terms of the effectiveness of the hypertext structure. The results indicate that object decomposition enhanced student performance on the exam but increased the amount of time required to complete the exam and the number of nodes visited. Given that enhancing student performance is a primary goal of education, the object decomposition-based hypertext provides a valid approach to designing and structuring educational hypertext.

Introduction

Background and the Problem

Beginning in 1994, CS383, Computer Systems, has provided access to over 1.2 gigabytes of course material through the World Wide Web (WWW). Hypermedia CS383 provides a vast array of media elements to support the transfer of information. The hypermedia course provides extensive resources such as: 143 audio files; 63 graphic files; 57 digital movies; instructor slideshows for every lesson; lesson objectives color-coded by Bloom's Taxonomy; note-taking guides; a course digital library system with over 470 student papers and slideshows from previous semesters; 300 pages of course hypertext with 178 cross references, 678 terms with pop-up definitions, and 600 terms that students can search on; an adaptive hypermedia interface that adapts the student's interface to the student's learning style; a Java and JavaScript-based for building and testing a virtual computer; and a DOOM scenario for administering cooperative quizzes in the classroom [Carver & Gregory 1995a, Carver & Biehler 1994a, Carver et al. 1995a, Carver et al. 1996a, Carver and Ring 1996a]. Through these components, Hypermedia CS383 attempts to enhance the educational resources available to the student outside of the classroom.

One of the key components CS383 is the course hypertext. Initially developed as a Microsoft Windows help file, this tool proved extremely popular with course students and typically students ranked it as one of the best tools in the course for learning (see Figure 1). The conversion of the help file to a WWW frame-based document provided the opportunity to re-examine the underlying structure of the hypertext. Given the popularity of the tool, optimization of the hypertext would maximize the effectiveness of student study.

The initial development of the hypertext was thorough yet only loosely structured around course lesson objectives and the course schedule. Research in hypertext development have suggested that object decomposition of the hypertext would facilitate student learning [Adams 1995a, Nanard and Nanard 1991a, Schwabe et al. 1996a].

---

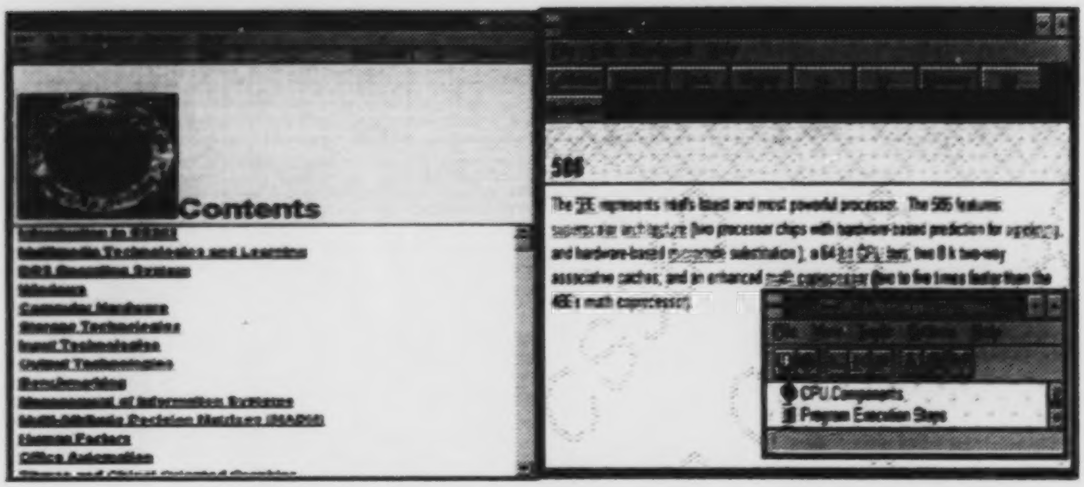

Figure 1: The User Interface into CS383 Hypertext and an Example Page

The Solution

During the Spring Semester of 1996, then a second version of the course hypertext was developed based on object decomposition. The content of both versions remained the identical; only the structure of the hypertext was altered. Both versions were then evaluated in terms of: student correctness on a ten-question exam; number of nodes visited; and time to complete the informational searches required to complete the exam.

Previous Work

Previous work has proposed methodologies for the development of object-based hypertext [Adams 1994, Nanard and Nanard 1991a, Schwabe et al. 1996a] without assessing the effectiveness of the proposed system. Other research has provided a subjective assessment of the effectiveness of the hypertext without quantitative proof [Carver & Howard 1995a, Ess 1991a, Landow 19??a]. Still other work have provided a quantitative assessment but used arbitrary segment decomposition instead of a structured approach such as object- or schedule-based decomposition as the basis for the study [Dee-Lucas 1996a, Dee-Lucas 1995a]. None of these works have examined quantitatively the effects of object-based structure on student performance using the system. In this regard, this work is significantly different from previous work in the field.

Methodology

Background

Both versions of the hypertext were developed using Wex-Tech Doc-to-Help. This forced certain constraints such as:

- The hypertext had a maximum of four levels.
- Due to the size of the hypertext, there was a maximum of twenty level one headings.
- The cross references within the hypertext can only point internal to their parent level one heading because each major section was a separate file [Wex-Tech 1995a].

The first constraint, only four levels of hypertext, had limited impact as providing more than four levels of hypertext would have increased the likelihood of user disorientation [Haga and Nishino, 1995a]. The second constraint, a maximum of twenty level one headings, likewise had limited effect as the course had only twenty-two major topics. Two of these topics were combined into related lessons. The last constraint, no cross references between level one headings, did have a major impact on the effectiveness of the hypertext. Often there were relationships between the course material in different level one headings but these relationships could not be connected through a cross reference because Word for Windows, the source of the help file, does not support cross references between files. Frequently, a text-based cross reference was provided so that the student could manually refer to the related material.

BEST COPY AVAILABLE

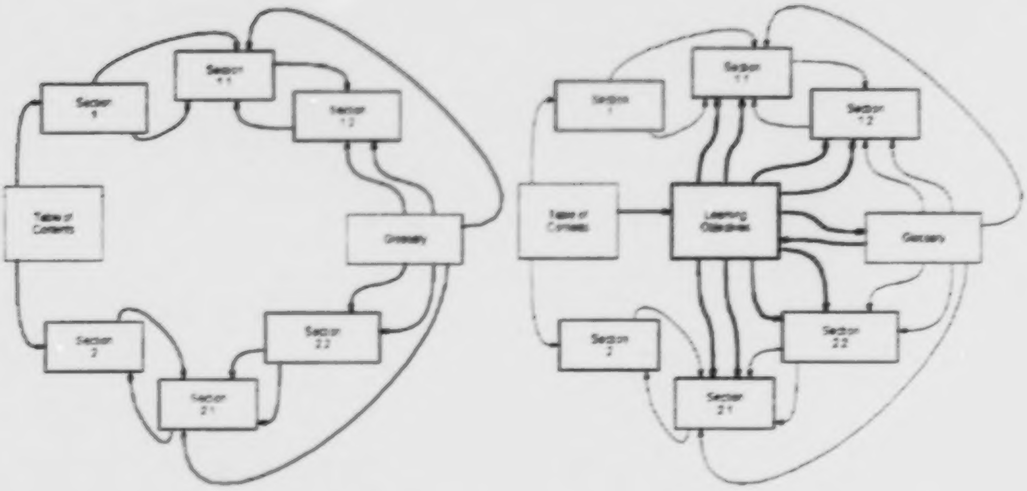

Figure 2: Course Hypertext Structure: Before and After

Using Doc-to-Help, two systems were developed to evaluate the effect of hypertext structure on student performance.

The original course schedule-based hypertext (CSBH) was structured according to the course schedule (see Figure 2.) Related lessons that occurred near each other were grouped together under a level one heading. Cross references between related material were built within the same level one heading. No cross references could be built between related course material in different level one headings. All four levels of the hypertext structure were used .

The structure of the second version (see Figure 2) was object oriented text decomposition based hypertext (OOTDH) [Talbert and Umpress 1989].

Restructuring The Hypertext

OOTD uses object decomposition to develop a hierarchy of relationships between concepts in the material. As a main concept is decomposed, the explicit relationships serve as links between the conceptual components. OOTD forces a hypertext creator to rethink several key development issues:

- How do I expect students to access this concept?
- What level of detail is needed at this level of abstraction?
- Can the student access material which supports or expands on this concept directly, or do they have to navigate through different hierarchical levels?

In an effort to assist a hypertext creator in systematically considering these issues, a methodology was developed which used OOTD and a set of graphical maps to depict the hypertext structure [Adams 1994]. Once concepts were decomposed into concept relationship pairs, these were displayed on an OOTD graph. Next, take the outline of the material (a hierarchical representation of the material) and display that in a graph form called a primitive linking (PL) graph. Combine the OOTD and PL graphs to create an initial system map or flowchart. At this point the explicit or first order links [Rada 1992] are displayed on the system map. The next step requires the hypertext's designer to portray the implicit relationships between concepts.

These implicit relationships sometimes appear in printed text as "See Section 1.23 for more details" or "Refer to Chapter 12". They are often the part of hypertext development that is not implemented because of the difficulty in tracking the links created by thoroughly cross referencing the material. By graphically portraying the cross references as well as the hierarchical links, a complete system map was developed.

This methodology had been used to create new Computer Assisted Instruction (CAI) material [Adams and Mengel 1996] but never to re-engineer an existing hypertext. A student group was recruited to re-engineer the CSBH using the aforementioned methodology. They began by completely mapping the relationships and links in the CSBH. They then created a thesis statement for the material in the

BEST COPY AVAILABLE

CSBH and designed a new structure for the hypertext. Using the Word for Windows documents that had served as the source for the CSBH and Doc-to-Help, the student group re-organized and re-linked the material. This effort ensured that the material did not change, only its linking structure.

The changes to the structure are calculated by measuring the Relative Out Centrality (ROC) of the hypertext system [Botofogo, et. al. 1992.] Briefly, a node's ROC is a measurement of that node's accessibility. The lower a node's ROC, the more accessible it is to the user. Hypertexts with high ROCs can have the problem of isolating information, i.e., constructing link paths that make it difficult for a user to locate and use information. A comparison of the ROCs of the CSBH and the OOTDH is shown in Figure 3.

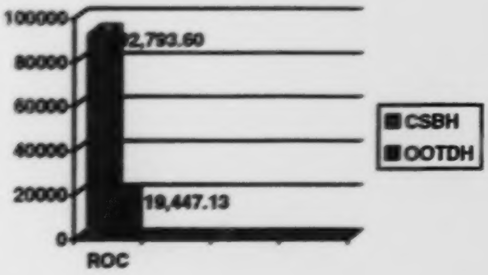

Figure 3 Comparison of Relative Out Centrality

Assessment Of Structure Effectiveness

Thirty-two students completed a timed evaluation of ten questions using the original hypertext and the hypertext. The students were timed in answering the questions, the number of nodes they visited were recorded, and the evaluations were then graded. The sample population of thirty-two students were divided into two groups: one which used the original hypertext and a second which used the hypertext based on object decomposition.

Results

There are two environmental factors that influence the results. First, the evaluation was given at the end of the semester and most of the students were comfortable using the CSBH while they had never used the OOTDH. Second, because it was the end of the semester, the students were also very familiar with the course schedule. These environmental factors should favor the CSBH over the OOTDH. Despite this bias, students using the OOTDH outperformed the students using the CSBH in certain tasks.

The students answered significantly more questions correctly using the object decomposition-based hypertext as compared to the course schedule-based hypertext. The students were correct 76.875% of the time using the OOTDH and were only 70% correct using the CSBH (See Table 1). Of the ten questions on the exam, students were more correct on five questions out of ten using the OOTDH, and were more correct using the CSBH on only two questions. Given that an increase in performance on a quantitative exam is a fundamental indicator that the students are learning more, the OOTDH provides a better structure than CSBH for pedagogical purposes.

This increase in correctness in performance is likely a result of the object decomposition. While both systems provide a deductive decomposition of information, the OOTDH system is more orthogonal and provides a finer granularity of knowledge representation.

OOTDH is more orthogonal in the decomposition of the course material than CSBH. Object decomposition provides a consistent framework for breaking the course material into manageable and interrelated nodes. CSBH is, at best, a loosely structured system with the determination of nodes and links decided by the professor. While the CSBH will more closely model instructor presentation of the course material, it may not portray the all of the links between course material and the number and size of nodes is arbitrary.

The arbitrary size of nodes in the CSBH system likewise affected student performance on the assessment. While there is no set size for nodes in a CSBH or OOTDH system, the OOTDH methodology often results in smaller nodes due to the object decomposition process. While this may lengthen the amount of time required to find the information, the fine granularity of the found information make it easier for the students to discern the correct answer. In terms of correctness, the advantages of the OOTDH outweighed the advantages offered by the CSBH.

Measurement	Course Structure-based Hypertext	Object Decomposition-based Hypertext
Correctness on exam (%)	70	76.875
Average time to complete a question (seconds)	67.279	84.631
Average number of nodes visited	4.913	5.107

Table 1. Summary of Results from Hypertext Evaluation

In terms of time and nodes, however, the students took more time to find their answer (67.279 versus 84.631 seconds) and followed more links (5.107 versus 4.913 links), on average, using the OOTDH as compared to the CSBH. This is likely a result of the close correlation between the student's mental model of the course material and the structure of the hypertext. The student mental mode of the course material is formed based the structure of the course and the presentation of the course material. Since the structure of the CSBH is based on the course structure, it closely matches the mental model of most students. Furthermore, as mentioned above, the students in the assessment had used the CSBH system throughout the semester and were familiar both with the course structure and the CSBH. This likely would decrease the number of nodes visited and the amount of time required to complete an exam question.

Summary And Future Work

Hypertext based on object decomposition enhances student performance on a exams but increases the amount of time required to complete the exam and the number of nodes visited. Subsequent testing is planned which is expected to show that familiarity with the OOTDH will decrease the amount of time required to locate desired information.

Future work is based on validating the effect of interface and network latency on hypertext effectiveness. This effort has spawned its own project which will be evaluating a distributed hypermedia product against a local hypermedia product and a standard text book.

About The Authors

CPT(P) William J. Adams

CPT(P) William J. Adams is an Assistant Professor in the Department of Electrical Engineering and Computer Science at the United States Military Academy. He is an active Duty Signal Corps officer with over 10 years service both overseas and in the U.S. Joe Adams has a Bachelor of Science in Computer Engineering from Syracuse University and a Master of Science in Computer Systems Engineering from the University of Arkansas. He is a member of the ACM, Upsilon Pi Epsilon, and AFCEA. His research interests include software engineering, hypermedia, and applied educational technology.

MAJ Curtis A. Carver Jr.

MAJ Curtis A. Carver Jr. is a student at the Command and General Staff College at Fort Leavenworth, KS. He is an active duty Army Officer with fourteen years of service. He has a Bachelor of Science degree from the United States Military Academy and a Master of Computer Science degree from Texas A&M University. Curtis is a member of Upsilon Pi Epsilon, Phi Kappa Phi, AFCEA, AACE, ASEE, and the ACM. His research interests include distributed multimedia, hypermedia, and object-oriented systems and network security. He can be reached at carver@eecs1.eecs.usma.edu.

5 Protocols to Electronic Mentoring

Jack M. Alpert Stanford Knowledge Integration Laboratory USA Alpert@skil. org

Abstract:

The factor that has most limited the development of a universal electronic mentor is that it is too large a task for any one group or institution to build. However, the web node model overcomes this largeness by allowing a very large number of people to collaborate. What they need to collaboration is 5 protocols that:

1) describe learning through hierarchical subgoals
2) standardize the learning interface of all nodes
3) describe the knowledge state of the mentee
4) describe context of the mentee's goal
5) keep a map of the return path through the hierarchy of goals.

Discovering five protocols

These protocols derive from any experience where completing the project required the learning of information. To complete the project you had to extract, assemble, and manipulate information from what you knew, and from a vast array of sources that included manuals, reference documents, peers, and classroom teachers. In that project, you succeeded but it nearly killed you.

Next time, what kind of help would you like? How about a little guy who sat on your shoulder and whispered short useful answers to your immediate questions. How about a little guy who would sit there all day and all night; waiting for you to ask never making you feel dumb or that your were wasting his time. How about a little guy that understood the problem you faced and the parts you already understood, and never wastes your time repeating what you already knew or adding extraneous information you didn't need. How about a little guy that was so smart he even knew when you could not understand the answer your needed. Instead of confusing you with gibberish he would say "you have to understand three things." We will work on understanding them first and use them to understand your question.

What you want is an ideal mentor

Forget for a moment that no single human being could be a universal expert in all bodies of knowledge. Forget that no single human could pay attention to your intellectual meanderings 24 hours a day for years. Forget the cost of paying an army of people who could perform such a task. And consider the list of capabilities that mentor or that army must have.

The ideal mentor lets the student set the initial goal, pick the time for learning, the pace of instruction, the duration of effort and not only allows random interruptions but reviews for the student the past progress at restart.

The ideal mentor knows everything and can logically and casually connect the mentee's objectives to first principles

The ideal mentor packages information so it:

1) is understandable with the knowledge the mentee already has,
2) appears useful in achieving the mentee's immediate goals. and
3) motivates progress through subgoals.

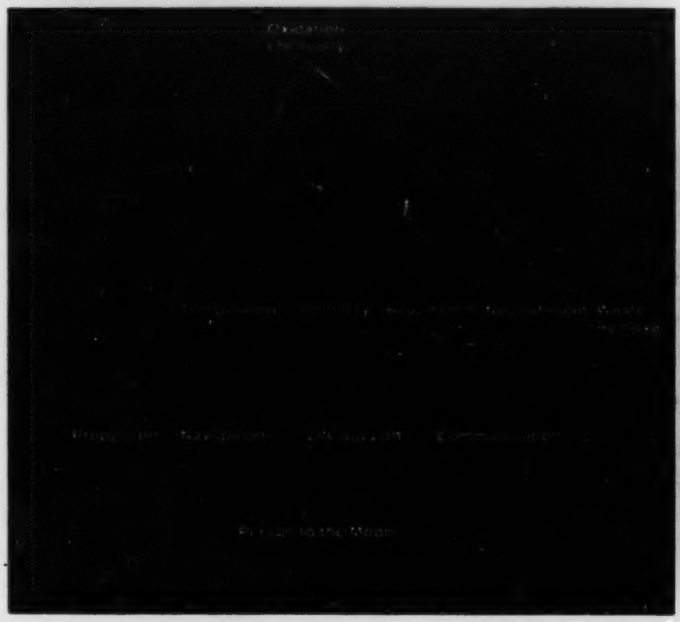
These packaging objectives are achieved by:

1) using a consistent and uniform presentation format
2) breaking complicated goals into smaller and smaller subgoals
   until the subgoals and their components are within the
   capabilities of the mentee.
3) limiting the content to the usable
   not broadening any explanation beyond that
   immediate framework created by the mentee.
      "The mentor has no syllabus."

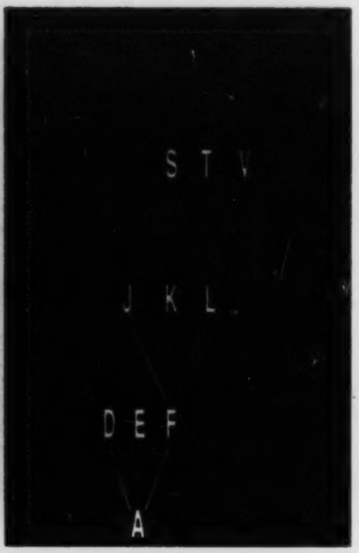
To facilitate this packaging, the mentor must have two measures and a map. The first measure is of the mentee's knowledge. The second, measure is that of the context of the mentee's goal. Finally the mentor needs a map to get the packages to fit together. The map shows all the subgoals previously visited and a record of their partial completion. The map keeps the mentor on a path to solve the global goal.

From mentor theory to web mentor

How do we convert this theoretical description to a web implementation. Our question is, "What parts of this ideal mentor are already inherent in web design and what parts need implementation." Let me pose an example problem, and then by tracing pathways to and through some subgoals of that problem make explicit both what activities a mentor is performing and deduce the electronic equivalent of them. Consider a mentee's goal of sending a person to the moon.



Oxidation
Chemistry
Temperature Humidity Respiration Nourishment Waste
Removal
Propulsion Navigation Life Support Communication
Person to the Moon



S T V
J K L
D E F
A

The mentor creates some subgoals. For example propulsion, navigation, life support, communication, etc. The life support goal can be further broken down into more subgoals. For example, temperature, humidity, respiration, nourishment, waste removal etc.

In general the goal tree will appear like A is accomplished if , D, E and F are accomplished. F is accomplished if J, K, L are accomplished. L is accomplished if subgoals S, T, V are accomplished, etc. The branches above these subgoals eventually lead to the laws of nature. The leaves on these tiny branches are definitions of single words in a sentence or definitions of single variables in equations.

The student progresses upward in the tree until the information presented makes sense and can be used to solve the next lower subgoal.

While these nodes are shown as part of a single tree, think of each letter as a web node written and maintained by a single expert.

In real life, an oxidation chemist mentor could play a role in solving many parts of the "person to moon" global goal. For example there could be pointers from the nodes of respiration, nourishment and even more distant branches like propulsion.

BEST COPY AVAILABLE

The oxidation chemist node being created independently of the man in the moon context, could also be pointed to from branches of trees representing other global goals. For example a heart transplant tree might have its blood gas branch pointing to the oxidation chemist node.

The operation of nodes

The node itself, must act like an expert mentor.

1) evaluate the mentee's current knowledge, and from this
    a) determine which group of subgoals if completed
    b) will allow the mentee to solve the super goal.
2) The node then facilitates the mentee's access to these subgoals.
    Finally the node must
3) verify its success. It has to know if it produced the understanding
required by the super node. If not, the node must create a remedial plan.

What the web can do

It is easy to see that the existing web structure accomplishes some of the impossible tasks in the ideal mentor list. For example the web can provide thousands of information sources. Make them accessible 24 hours a day to thousands of mentees. The web can present information using voice, text, symbols, pictures, animations, and simulations

Five problems to be solved

However, in its present state the web can not facilitate efficient mentor based learning To accomplish this it has to overcome 5 problems.

Problem 1 -- The nodes don't work together.

The designer of a node must find it easy to locate subnodes which efficiently support learning to complete the super goal. This efficiency can only be accomplished if the nodes are designed using the same learning model which explains how to break goals down into sub goals. Until this learning model exists each node maker will design his own, making it harder for others to use them. Each node designer will include activities that should be in a sub node with his node. That node will grow. The job of creating and maintaining such a large node will be difficult. Few if any will want to attempt it.

Thus to keep things distributed in small manageable nodes requires a protocol that tightly defines learning through hierarchical subgoals

Problem 2 – Non standard GUI

Students need a standard view of information that let's them navigate through their learning environment. That is they need to steer from topic to topic, parse confusing presentations, learn the supporting concepts, repeat an explanation, evaluate their comprehension and stop and restart their learning. The user interface must make this easy. If every node builder implements a unique interface, the mentee will have to learn the node's interface before starting on the node's content. The overhead will greatly reduce the electronic mentor's value. To prevent such hardship a second protocol is required which defines a single standard interface.

Problem 3 - node's ignorance of the mentee's knowledge

A third problem was created when we switched our mentor from a life long friend on our shoulder who was familiar with our unique objectives and capacities, to an army of independent mentors who are strangers. If each mentor has to start from scratch to establish our knowledge and capacities, valuable minutes and possible hours could pass before they could lay block one of their plan to help us.

The resolution of the third problem is the design of a byte code protocol that defines each user's capacities and knowledge. A byte code that could be read by each node and modified by each node when the mentee learns new knowledge.

Problem – 4 node's ignorance of the context of question

A fourth unresolved problem, is that a sub node needs the context of the super goal to do its job. What the little guy on your shoulder had, a lifetime of experience with the mentee, the sub node designer has to gain from an interview with the mentee. The resolution is a protocol that allows the super node to create a digital code for the problem's context. and passed this code to the subgoal with the mentee.

Problem 5 – no one is keeping track of the learning path

For hierarchical learning to work a sub node must know to which node to return the mentee to after it completes its work. Once returned to a super node that has several subnodes there must be a record of which of these sub goals have been completed and which remain yet to be done. To solve this problem you create fifth protocol which contains the address and completion information for each active node in the tree. This data structure resides in the head program, which is located on the individual's home computer or service provider server.

Summary

Thus we have come to the end of our story. What needs to be added to the existing web scaffolding are 5 protocols.

Protocols for:
1) describing learning through hierarchical subgoals
2) standardizing the learning interface of all nodes
3) describing the knowledge state of the mentee
4) describing context of the mentee's goal
5) keeping a map of the return path through the hierarchy of goals.

The factor that has most limited the development of a universal electronic mentor is that it is too large a task for any one group or institution to build. However, the web node model overcomes this largeness by allowing a very large number of people to collaborate. And what they need to collaboration are these 5 protocols.

Conclusions on the Analysis of User Requirements concerning the use of ICT in the Didactic Process

Abstract: The co-operation of the Information and Communications Technologies (ICT) and the Educational Society, is deemed necessary for the adaptation and tuning of the didactic process in terms of pedagogical methodologies, school infrastructure, human resources utilisation and organisational restructuring. The use of ICT in the classroom should be viewed as a highly influencing tool that will support the educators' effort for interaction with their students, rather than as a technical exercise. The initial phases of the TRENDS project, which are described in this paper, resulted in a widely accepted common methodology, that complies with the international standards for determining the User Requirements in the Secondary Education. The major results emerged from this survey are presented here, as well as some common axes that deal with the application of ICT in the didactic process.

1. Introduction

It is nowadays more than evident that the rapid evolution of the Information and Communication Technologies (ICT) during last decade, along with the need for widespread distribution of knowledge, have necessitated the development of pioneering distance education services for the assistance of the didactic process. The collaboration of these two distinct worlds - Computer Science and Education - will result in the creation of a universal Education Society.

The distance education services are expected to find major fields of applications in the didactic process, since they attempt to exploit the benefits that ICT offers in Education, rather than make the educators and the trainees experts on ICT. Yet, the co-operation of these two communities is not straightforward. Experts from both worlds will have to participate in joint projects which will consider the needs and the trends of both sides and will end up with a unified distance learning environment. Such an environment must support multimedia information, such as plain or formatted text, still images, audio and video, especially since it is addressed to people with no experience in using computational environments in their professions. The new age of training via networking will aid the wide distribution of knowledge and the construction of live, virtual classrooms, as well as widely accessible databases of courses on various subjects. In these classrooms, the students will participate in the training process by inquiring or interacting with the educators, while the off-line courses will be accessed and played independently by the trainees.

A measure of success for a distance learning environment would be the use of computers not only as electronic typewriters and spreadsheets, but as research and educational tools. Another indication of success would be to see educators integrating their lectures with student interactive learning procedures, and learning how to intermix them effectively. Since they aim to serve many target groups of various interests and aspects, the distance learning environments should be user friendly and to cover subjects from multiple areas and also multiple levels of trainees. In order to achieve user friendliness, a serious task of a project is the Users Requirement Specification.

There have been significant projects in the area of Distance Education. In [Veen et al.] there is a review of a range of communication and information technology projects within and across European countries. Most of them describe the collaborative use of electronic mail between schools on an international level. Ruopp et al. ([Ruopp et al. 93]) describe an in depth and long term project called LabnNet which attempts to develop a community of practice among teachers for supporting each other's profession across the USA. Companies such as AT&T have become involved in the development of services under the guidance of experts. Attempts have also been made to quantify the benefits of such electronic information and communication services. For example, [Riel 94] provides evidence related to the development of the skills that employers wish to see in their new recruits.

2. The TRENDS project

The *TRaining Educators through Networks and Distributed Systems (TRENDS) Project* [Bouras et al. 96] aims at the in-service distance training of 2,400 school teachers in Secondary Education, on the "*use of Information Technology and Telematics in the learning process*", from six countries (400 per country) - France, Greece, Italy, Portugal, Spain and United Kingdom. The training process will be implemented by flexible and distance learning methods, through:

- The development and the use of an in-service, school-based training session, which will be based on multimedia telematics and existing, mature network technologies.
- The establishment and operation of a European Teachers' Training Network (ETTN), consisting of six interconnected "National Sites" (a Training Centre, clients in the schools and teachers in each country) and providing distance training services, by using multimedia telematics, to teachers and teacher trainers.

During the TRENDS project 120 teachers - one from each of the 120 participating schools - will be trained in the early validation phase, and will traine the rest of the 2,400 teachers afterwards, in the project demonstration phase. The evolution of a promising and ambitious experiment, such as the TRENDS project strongly depends on the strategy and the "Usage Scenario" that will be adopted. Thus, it is of great importance to specify the User Requirements effectively, covering the needs of both the direct users (educators who will participate in the project) and the indirect users (policy makers in the Education System, ICT experts, etc.).

3. Methodology for the User Requirements Specification

The target group of the TRENDS project is trans-European and consists of educators who will be trained on using Information Communication Technology (ICT) in the classroom. Some of the possible techniques that could be used for the establishment of the User Requirements of a trans-European project, according to a widely accepted methodology (eg. [Smith & Mayes 96]), are the following:

Personal interviews with the end users. This technique offers a useful way to investigate the User Needs in real life. The main problem is the enormous number of the end users, which might lead to prohibitive costs. A careful selection of a representative group of the initial target group of the project might aid such a procedure to be more practical and still effective.

Questionnaires. In order to keep the cost down, the use of custom designed questionnaires and surveys may prove a more practical option. The key point of this technique is the construction of the questionnaires, so as to be representative and to reflect all the possible user requests. The team that will construct the questionnaires must include specialists on the scientific areas that the project deals with, experts on technological issues, as well as representatives of the potential target group.

Organisation of discussion panels for brainstorming and feedback. In these panels, representatives from all sides of the project should participate, for a more objective overview of the situation. This might be useful as a final stage, for verification of the User Needs as they were described by some other technique.

After some co-ordination among the partners of the TRENDS project, some common points emerged from the methodologies for the specification of the User Needs per participating country. These common points were agreed to form the following widely accepted methodology:

1. Interviewing of a number of representatives or key persons of the target groups and experts per country, for a first impression before constructing the custom designed questionnaires.
2. Construction of workshops of key persons for discussion on topics related to the strategic plan of the project.
3. Construction (according to the information provided by the steps 1,2 of questionnaires, and distribution to the potential end users (teachers of schools). These users were categorised in two major groups:
   - Users with experience in using ICT for educational purposes from a limited number of schools
   - Users with no experience in the use of ICT.

4. Presentation of Results

The survey that took place during the TRENDS project, aims to provide the project with clear ideas for the skills/expertise the teachers must acquire through accessing the foreseen TRENDS distance training services. The outcome of this survey will safely lead to the determination of the "Functional Specifications of the Network".

According to the adopted methodology, a number of workshops/round table discussions and interviews were organised firstly, in order to have a starting point and a global view of the user needs, before constructing the questionnaires that were eventually distributed to the potential end-users of the project. In some countries two kinds of questionnaires were distributed, one for the experienced and one for the inexperienced users [TRENDS, Bouras et al. 96].

The kind of participants in the workshops/round table discussions and the interviews, differed among the national sites. Among the participants were, university professors, key persons in education policy making, national experts in ICT and Open Distance Learning (ODL), teachers experienced in the use of Telematics in secondary education, etc. In some national sites a common questionnaire was used for the interviews.

The participants of the workshops/round tables focused on key issues related to the teachers' job profile, his/her initial and in-service training, the "new role" of the teacher implied by the introduction of the new technologies, the needs for support, and the access, cost, management and suitability of the new technologies. The results extracted from the interviews, concern educational policies, the content, forms and aims of further training, and the functional scheme of distance teachers' training on the use of new technologies.

It was concluded that in order to create better conditions to promote the involvement of the educators in TRENDS, it is important to:

- give to the schools better conditions for the kind of activities involved in TRENDS (provision of appropriate classrooms, access to Internet, etc).
- motivate the school teachers (ie. by providing courses focusing on their own interests)
- create or adopt interfaces and user-friendly services
- create a group of users specially prepared to promote the use of the telecommunications services.

In order to satisfy the training needs indicated by the teachers, it was suggested that it is important to develop courses or other initiatives that focus on the following aspects:

- educational methodologies for specific subject areas
- pedagogical issues
- management and implementation of educational projects
- application of information and communication technologies
- integration of information and communication technologies into the curriculum
- provision of essential know-how on using basic telecommunication services such as e-mail, news, fora, bulletin board systems
- development of basic skills on the use of co-operation tools over network infrastructure
- development of basic skills on constructing WWW pages (eg. HTML editors)
- educational potential created by the use of telematics services, either privately or in the classroom

In order to upgrade the educational system, the need for further education and the utilisation of new technologies should be highlighted. Moreover, the teachers should become more acquainted in researching methods and not only skilled in using learning technologies in order to bridge the gap between the degree of technological complexity and the real didactic innovation. The most appropriate way to accomplish this is via small groups or on an individual basis.

Educators should also learn to familiarise themselves with the new educational methods. Different forms of training should applied and co-exist, eg. seminar type, distance training, schools-based, at home. The majority of teachers believe that long distance training should be accompanied by some form of interpersonal communication and contact with other teachers. The vast majority of teachers said they prefer the combination of training with the use of computers and the distribution of related literature.

The experienced users said that their current personal usage of ICT was high, indicating that they used ICT to produce learning resources and for administrative purposes. This usage is less concerning the use of ICT in their lessons. At school the greatest use was in a departmental room, spreaded throughout the day.

Training at school should provide the student with the opportunity to "construct" the new knowledge within an appropriate technological and learning environment. The contact between the trainer and the trainee should make use of all the capabilities offered by modern technology. Another important issue is the development of courses aiming to help teachers to cater for those students whose performances are not satisfactory.

While there is a prevailing use of off-line technologies, the demand is oriented toward on/off-line technology (in the educational and teacher training environments). Among the on-line technologies the prevailing interest is for E-mail and WWW servers, while among the off-line options the prevailing interest is for teaching software and applications. Nearly all teachers would like to collaborate with colleagues from other countries and receive information on European educational programs, mostly for aspects related to the subject taught.

The general attitude of the inexperienced users towards the use of new technologies is quite positive. Most of them said that are particularly interested in initiatives regarding modalities of using new audio-visual and multimedia learning tools. Most teachers prefer to be trained through examples of real applications, or through a combination of theoretical presentations, empirical applications and suggestions on existing literature on the subject. Also, the interviewees seem to be particularly interested in the professional updating of teachers and in the Consultation of encyclopaedia, atlas, dictionaries, reference books.

5. Comparative Analysis of Results

5.1 Introduction of ICT to the Educational Process

First of all, with their all-encompassing approach regarding the specific needs of educators, the countries participating in the project illustrate the principle that training in the use of information technology is not the project's main purpose. The main aim is the familiarisation of educators with the use of ICT as a supporting tool for the educational process. Within the same context is the realisation that the further education of teachers in the field of ICT will improve their professional skills, change their teaching habits and give them a more positive profile which will contribute to the improvement of the quality and efficiency of their work.

Since the educational background of teachers in the use of the new technologies is deemed inadequate, it is necessary that they undergo an initial basic training course on ICT and its capabilities as a teaching tool. In most countries - Spain, Portugal, Greece, France - these needs revolve around certain facets of ICT.

5.2 Application of ICT to Didactics

Nearly all countries have exhibited the need for additional scientific knowledge pertaining to particular subject matter. This knowledge ought to either fill in ascertained gaps in the initial training of educators or contribute to the updating of the educators on the subjects they teach (Italy, Portugal, Spain).

Certain countries (Italy and Portugal) have proposed the introduction of parallel training programs for the interdisciplinary approach to the lesson being taught. The aim is to diffuse knowledge among the users of the TRENDS network. For this purpose, the training model must be as open as possible and satisfy wider pedagogical, scientific and social needs. Within the same framework are:

- The need for further updating of educators on the new didactic methodologies that are developed and applied to each subject matter, is deemed imperative.
- The need to learn ways and methods in order to readjust the didactic methodology used by educators in the wake of the new knowledge they will have acquired and the new skills derived from the use of new applications within the context of ICT (England).
- The need for the provision of additional knowledge regarding pedagogical theories that can be applied in real everyday school situations (Portugal).
- The need to update and educate the students in the new evaluation methods (Greece).

5.3 Needs of End Users for the adopted Training Model

The development of an environment favourable to communication with a content which is of interest to the educator who uses the services offered to the TRENDS users, has been deemed necessary for educators. This conclusion has emerged from the research carried out in many countries (Portugal, Spain, Italy, France). Educators need to communicate on matters regarding: 1) information about the innovations in education, and exchange of information between the users of the system, and 2) update on the organisation and application of educational procedures aiming at the dissemination of better teaching attitudes.

It has emerged from the research carried out in Greece that there is a need for the provision of information on the organisation and functioning of other education systems. The capability to exchange educational material and experiences on the use of ICT is also required. The proposal that students should also be given access to this information is noteworthy. The establishment of these terms of communication will promote, among other things, a European dimension in education (Italy, Spain).

In certain countries educators prefer to be trained within the framework of the school system rather than through on-line communication with the trainer (Spain, Italy). Yet, on-line communication with the instructor (and with colleagues on a national and international level) is generally viewed as a necessary prerequisite. The occasional direct communication between the educator and the trainer is equally important.

Several countries (eg. Italy, Spain), lay stress in the participation of the entire school community (students, teachers etc.) in the TRENDS network. Other countries (Greece) favour both the individual and the group procedure. It has been proposed that groups should comprise people sharing common interests. According to conclusions made in Italy, educators with a different background can only be grouped together, if the sole purpose is to learn the general uses of technology as opposed to using it as a teaching aid for specific lessons.

In several countries (eg. England, France, Portugal) it is generally believed that the educators undergoing further training, who will in turn train their colleagues, that they should have some form of knowledge and experience on ICT, good relations with their colleagues, a positive attitude to ICT and strong motivation.

As for Italy, experts and those from the target group, who are experienced in the use of ICT, prefer to be linked up from their homes. Others, less experienced in the use of ICT have expressed an interest in working both from home and school on the basis of a flexible time schedule.

The provision of sufficient incentives for educators participating in the TRENDS project constitutes one of the more critical aspects for its success. One category of incentives referred to by educators and experts of all participating countries concerns the provision of substantial help to educators to carry out their work. It also entails the opportunity to work with colleagues and students beyond the confines of regional limitations, and access to information sources, the opportunity to develop common projects and initiatives with other educators and bodies outside the field of education. Finally, educators must be able to take advantage of the benefits provided by long distance training (flexibility, speed) and fulfill their professional ambitions.

6. Conclusions

The synthesis which has been attempted in order to illustrate the basic common needs of educators in the TRENDS project, led to the following conclusions:

- The use of ICT in the teaching process seems to be promising and beneficial.
- The programme should not only furnish supplementary knowledge on the subject taught, but also provide guidelines for interdisciplinary approaches on common matters.
- Information should be provided on the use and opportunities provided by access to educational material databases, documentation centres, electronic libraries etc.
- ODL is a method accepted by the majority of the members of the target-groups in each country.
- On-line communication between the educators and their trainers and colleagues is generally viewed as an elementary tool and essential precondition.
- The combination of vision, text, sound, video etc. is generally considered necessary, as is the use of WWW server, e-mail, news, video-conferencing etc., along with some relative printed literature.
- The TRENDS network would rather use existing communication technologies (eg. Internet, Euro-ISDN).
- Schools are generally accepted as the training grounds, provided that some infrastructure problems are solved. Many educators however have expressed the interest to undergo, when feasible, training at home.
- As for some incentives to participate in the programme, it is advisable, apart from strictly educational considerations, to examine others such as training certification, accommodations with respect to the work schedule at school, financial benefits, etc.

Abstract: In this paper we present a distributed HypERMEdia SERVICE (HERMES SERVICE) which supports integrated capabilities for distance education and learning purposes. Hermes service consists of hermes servers and hermes browsers. The users are connected with the service using hermes browsers and retrieve hypermedia lessons organised in thematical units. The lessons are stored in various distributed Hermes servers which retrieve the requested lesson and transmit it to the corresponding browser on on-demand basis. The requested lesson is presented to the user according to a well defined presentation scenario. The media objects are rendered in a synchronized manner according to the spatio-temporal relationships existing among them. Finally, special monitoring mechanism controls the state of the network and adjusts the presentation process so as to improve presentation quality.

1. Introduction

During this last decade we have experienced a new trend towards teletraining. The need for teletraining systems has been mentioned from the early eighties, but with the advent of this decade, the evolution of multimedia technology in conjunction with the new perspectives that the networking technology has brought, provided new potentials for the development of teletraining systems.

This new challenge will play a significant role in the near future, as it will be possible to access education, training and retraining whenever and from wherever required by the learners. This novel way of training motivated us to design and implement this distance education service. The scope of the service is to provide to the user a set of functionalities for retrieval and browsing of lessons which are stored in various distributed servers.

Our proposed service provides a number of advantages which can be summarised in the following points :

- *transparency*: the user focuses on the service and the provided lessons, while internal information regarding the distributed organisation of the service and the interconnection of the various computer systems over the network are hidden
- *ease of use*: an integrated and friendly graphical environment, implemented in various platforms, provides the user the necessary capabilities to interact with the service
- *on-demand delivery*: the requested hypermedia lessons are transmitted on on-demand basis and not on store-and-forward mode, and as a result good performance is achieved, while the needed resources are reduced [C.Bouras et al. 1996b]
- *resource management*: special monitoring mechanisms are included in the service in order to detect network bottlenecks and presentation anomalies. Using these mechanisms the needed resources are dynamically reserved [C.Bouras et al. 1996b]
- *integrated presentation environment*: the presentation of hypermedia documents is done in a well structured environment without the external invocation of presentation "players" [R.Steinmetz 1990]
- *search capabilities*: the user may search for topics of interest and retrieve the matched items avoiding the selection of a particular lesson
- *subscription-authorisation mechanisms*: the user must be member of the service in order to have access on it. Therefore, non-authorized users are not permitted to use the service
- *compatibility with the WWW and e-mail facilities*: the user may also browse html documents, send and receive e-mails. This capability is considered useful in order to communicate with the constructor of each lesson and ask additional information on themes of interest
- *flexible and modular design*: the design of the service is performed having in mind the embodiment of new functionalities and the provisioning of variety of media formats. The followed design approach is the object-oriented.

2. Architecture Overview

The architecture of Hermes service is based on the client-server model. The basic components that comprise it are the following ones:

- *Hermes server* where the lessons are stored. For every lesson a presentation scenario is associated. The presentation scenario of a lesson actually describes the spatio-temporal relationships among various media objects. The inline media objects are stored in the corresponding media servers. When a request for a specific lesson is triggered, the specific server where that lesson resides on, is contacted. The server searches the database of provided lessons and locates the requested lesson. When the presentation scenario is found, Hermes server activates the involved media servers in order to start the transmission of the corresponding media objects which are referred to the presentation scenario on on-demand basis.
- *Media servers* in which media objects are stored. For every media object (e.g., text, image, audio, video, etc) a media server is associated with each Hermes server. These media servers may be located in the same host with the Hermes server and each one is responsible for transmitting a certain media type through a parallel connection which is established between the browser and the corresponding media server. The involved media objects are transmitted from the media servers towards the browser according to the presentation scenario and the presentation constraints. The transmission process of each media object is adjusted according to the feedback reports which are sent by the Hermes browsers and describe the status of the network and the presentation process.
- *Hermes Browser* is the integrated graphical environment through which the user interacts with the service by retrieving and browsing lessons. The browsers may run on a multimedia PC and facilitate all the provided functionalities of the service. The browsers also manage the synchronized presentation of the requested hypermedia lesson. Internal mechanisms monitor the status of the network and report the network and synchronization anomalies to the corresponding Hermes server and media servers in order to adapt the transmission rates. In that way, the presentation quality is significantly improved while the needed resources are dynamically reserved.

3. Functional Description

Since Hermes is a service designed to be used from users, we focused on *simplicity* and *functionality*. In the sequel, the basic features that make Hermes Service a useful and attractive service for educational purposes are introduced.

- Connection-Subscription with the service
- Search for related topics
- Viewing a lesson
- Off-line interaction between the tutor and the users

3.1 Connection-Subscription with a Hermes Server

The connection primitive is the first action that the user must follow in order to access the service. Initially, the user must specify the Hermes server that desires to connect to. For that reason, a list of available Hermes servers is provided. For every Hermes server, a small description concerning the kind of lessons that are stored in it, is presented. Every Hermes server contains lessons concerning specific and well known thematical units. Therefore, the user may easily access the server of his preference. When the user specifies the Hermes server that desires to connect to, an authentication process takes place in order to verify whether the specific user is authorised to use or not the service. If the user is not an authorized one, he is requested to subscribe to the service filling a subscription form as it is depicted in Figure 1. The subscription form contains various information, such as the real name, the address, the postal and e-mail address and telephone number of the user. A coherent, centralized database of authorized users is updated, and from now on the user may easily access the service. Whenever a user is connected with the service, the database of the authorized users is updated and specific information about the exact time logged in the service, as well as, the lessons that are retrieved are captured.

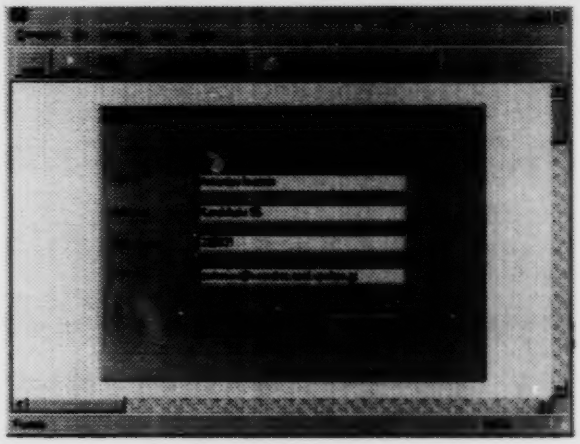

Figure 1: The Subscription Dialog Box

3.2 Search for Related Topics

In case the user is interested in a certain topic, he is able to search the contents of the *whole* service by invoking the search primitive. In particular, the user specifies the search token which best describes the topic of interest, and selects the server that is likely to contain lessons on the topic. The user selections are transmitted to the specified server and in the sequel, all the text documents stored in that server are scanned. Additionally, this particular server sends the query to all other Hermes servers for the same reason. In every server the same procedure is performed. The results of the query on every

BEST COPY AVAILABLE

server are forward to the initial server and then directly to the user. It must be noticed that only the lessons which contain the item of interest and the server location are transmitted and presented to the user. In that way, the user may search the contents of the service and retrieve only specific lessons on particular topics, avoiding the navigation through all the provided lessons. In addition to that, the user using a friendly dialog box, as shown in the following Figure 2, can specify the search options.

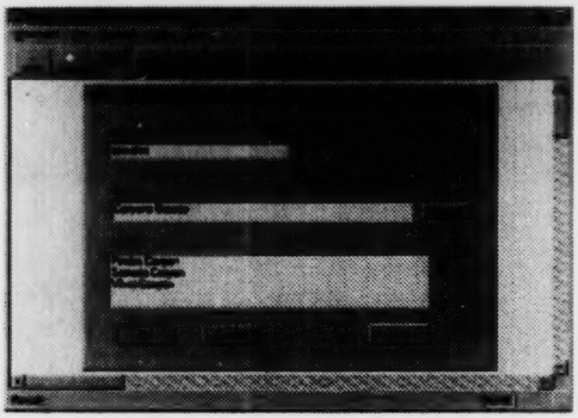

Figure 2: The Search Dialog Box

3.3 Viewing a Lesson

After the connection has been established, a list of available lessons which are stored on that server are presented to the user. The user may select a specific lesson from the list by "clicking" on the corresponding hyperlink. In that case, the request is forwarded to the server. The server upon request retrieves the presentation scenario of the lesson and determines the inline media objects as well as the spatio-temporal relationships among them. For every media object referred in the presentation scenario, the server determines the media server at which it is stored, and specifies the transmission requirements for that object. Consequently, all the associated media servers are contacted and the transmission requirements for every media object are explicitly determined. Every media server, builds a parallel connection with the browser, retrieves the media object, transmits the data on on-demand basis based on the transmission requirements. During the transmission of the media objects feedback reports are sent to the involved media servers and the Hermes server in order to adjust the transmission rates or the enconding format.

At the browser site, the presentation scenario of the requested lesson, which is sent by the Hermes server, is scanned and the needed resources are reserved. Every media object is temporarily stored inside the buffers, and then is presented to the user according to the presentation scenario [Chun-Chuan Yang and Jay-Hsiung Huang 1996], [Herng-Yow Chen and Ja-Ling Wu 1996]. The browser during the transmission of the hypermedia lesson, collects information about the network status and the presentation quality, i.e. the presentation anomalies that may occur.

From the application point of view, the user may follow sequential or explorational links. The sequential links specify a coherent view of the lesson, i.e. the tutor's way, while the explorational links are relative to theme hypermedia documents with additional information on specific topics. In both cases, the browser manages the user selections in the same way. If the selected lesson or topic is stored on another server, a suspend connection primitive is invoked, and a request for a new connection with the new server is triggered. The suspended connection remains active for a period of time in case that the user requests to view a previously selected document. When this interval is passed, the connection closes and the attached client is informed about the event. At that time the client has an active connection with the new server. At any time the user may disconnect from the service by "clicking" on the appropriate button.

The user interacts with the application using a fri
r interface thathandles all his requests. It also
avigation option through the differenthypertexts.

Application Functionalities

As far as the authoring tool is concerned it will
friendly way of constructing hypertext lessons." Sup

Figure 3: The Browsing of a Lesson

Among the several facilities that can be supported by the browser are the following ones:

- Moving *back* and *forward* in the list of already viewed lessons. This can be achieved with the use of menu buttons.
- *Scrolling* of the hypertext document.
- *On-line help* provision.
- *Interactive* operations can be triggered during the presentation of the lesson. The user can pause the presentation of the lesson and resume later from the point that it was paused via control buttons.

In

Figure 3, an example of the browsing process is given.

3.4 Off-lineInteraction Between the Tutor and the Users

In case the user wishes to make comments or submit questions concerning a lesson, he is able to use the e-mail service offered by Hermes. The user can send e-mail to the tutor asking for additional information about a theme. In that case, the tutor can send replies to the user prompting him/her to retrieve specific lessons from the service. Using this off-line mechanism an immediate connection between the user and the tutor is achieved and as a consequence, the educational activity is improved. Therefore, the user may avoid the useless navigation through relative but not specific lessons of interest.

4. Implementation Issues

The Hermes server has been developed under the Unix operating system using the facilities offered by OSF/Motif, Xtoolkit and Xlib. On the other hand, the Hermes browser has been implemented both under the Windows 95 operating system using Visual C++ version 4.0 and the Unix using OSF/Motif. The implementation of the network support primitives that are needed for the realisation of the on-line operation is based on the TCP\IP protocol suite. The hypermedia presentation scenario is transmitted through TCP connections, the non time sensitive media objects (e.g., text, images, graphics) are sent under TCP connections, and the time sensitive media objects (e.g. audio, video) under UDP connections. We utilize the UDP connections for the time sensitive data in order to avoid the additional delays introduced by re-transmissions. Although the UDP is not a reliable protocol, it seems that adequately meet the requirements for real-time sensitive data. In addition to that, the network connections for the control data are transmitted through TCP connections. The underline network infrastructure is an 100 Mbit/s FDDI ring which is able to support on-demand service. Despite the fact that our service does not based on quality of service guaranteed networks, the adaptive nature of the

BEST COPY AVAILABLE

service in conjunction with the network monitoring facilities may significantly improve the presentation quality.

Furthermore, we used the Real-Time Protocol -RTP- [H.Schulzrinne 1995] as a transport vehicle suitable for transmitting time sensitive data. The RTP\RTCP resides between the transport and the application layer and are designed to be independent of the underlying transport and network layer. We used the RTCP protocol for the transmission of the control data, and the RTP protocol for the transmission of the presentation scenario and the inline media objects. The RTP protocol provides end-to-end delivery services which include payload type identification, sequence numbering, timestamping and delivery monitoring. The RTP itself does not provide any mechanism to ensure timely delivery or other quality-of-service guarantees, but relies on lower-layer services to do so. The RTP control protocol (RTCP) is used to transfer feedback monitoring reports concerning the network status and the presentation anomalies.

For the description of hypermedia lessons we implement a hypermedia, html-like markup language with simple synchronization primitives. Using that language the tutor can explicitly specify the layout of the hypermedia lesson and the spatio relations between media objects. In particular, special keywords for the text formation, the figure and graphics placement are provided. In addition to that, the constructor of the lessons may also specify the temporal relations among the inline media objects, like annotated text.

The system has been installed and successfully tested on a variety of SUN SPARCstations and PCs with different memory and processing power characteristics. The system can efficiently operate over LAN and WAN networks.

5. Conclusions and Future Work

Hermes service can support the distance education process bridging the gap that is created by the geographical distances that separate users from tutors. Its real-time characteristics along with the attractive user-interface make it a useful service for realising the purpose of distance learning.

Hermes service provides an integrated graphical environment for the synchronised presentation of hypermedia lessons which are stored in distributed Hermes servers. Additionally, the included searching capabilities and e-mail facilities constitute our service an integrated educational environment which helps the user to acquire the topics of interest with a friendly and transparent way. Finally, Hermes browsers can present html documents, and as a result compatibility with the WWW is achieved.

In the future, we intend to incorporate special mechanisms for efficient information retrieval, to support the presentation of MHEG hypermedia-like documents, and to implement network interfaces for quality of service guaranteed networks like the ATM.

ABSTRACT:

This paper describes developments looking at the application of technology and telecommunications in rural government secondary schools in Victoria, Australia Schools involved in the projects are at least 150 kilometres from Melbourne, the capital of the State, with most of them being more than 300 kilometres distant. These schools deal daily with the tyranny of geographical distance and the associated difficulties of endeavouring to offer a wide selection of curriculum to their students. The issues rural schools face generate some innovative methods for connecting teachers and students in curriculum delivery and in the exploration of alternatives approaches to teaching and learning.

The presentation will briefly detail some of the experiences of the clusters of schools adopting technology approaches to curriculum delivery; the management structures adopted; the attributes of co-operation and collaboration which characterise their work in the joint delivery of curriculum; the technology facilities available to schools; the curriculum subjects on offer and strategies used by teachers in adopting alternative approaches to teaching, learning and curriculum delivery. Finally the paper will briefly discuss training for teachers, evaluation to date and future plans.

Introduction

The use of electronic technologies in facilitating rural education is not new in Victoria. Seventyfive schools in isolated areas of the State have been working in clusters or groups of schools for over ten year (Marghitta, 1989, Conboy, 1989) to deliver curriculum by electronic means. Until recently the predominant technologies have been audio (phone conferencing) or Telematics/audiographics (MacFax-Duct; Electronic Classroom software (Elliott,1992). However more recently many schools are integrating facilities offered by the Internet and in 1996, twenty seven schools acquired full videoconferencing facilities, which are currently being implemented in various configurations.

A Little Bit of History: The Original System

Victoria is a southern State of Australia with 780,000 primary and secondary students in 2,300 schools. The State has a dual system of State and private education. The State system caters for 528,000 students with 1340 primary schools and 400 secondary schools. State and prhate schools cater to the needs of both metropolitan and rural communities.

In 1983 an Australian government report, known as the Burdekin Report, into school retention rates in senior years found that students in rural schools were less likely to remain at school for the final two years of secondary education. The major reasons for this were identified as the lack of choice of subjects in the curriculum and a shortage of specialist subject teachers in country schools, especially in the Science & Technology and Languages other than English (LOTE) areas. One solution to this problem was explored in the trialing of electronic telecommunications in remote schools to share teacher expertise across clusters of schools, thus widening the subject choice for students in these rural schools (Conboy, 1992).

Teachers worked on an 'extended classroom' model of communications and delivery, an early 'open learning' model in which the 'walls' of the classroom were viewed as the boundaries of learning. The same methodologies and approaches to teaching and learning as were used in the classroom, it was assumed, could be applied in asynchronous communication in distant environments with the assistance of appropriate technologies. The technologies were again identified within the framework of the group-based teaching approaches of the traditional classrooms.

'Telematics' was the term used originally to describe the application of electronic telecommunication for distance education in Victoria. Whilst later deHmitions (e.g. Hill, Meulenberg, McNamara &: De Wildt, 1991) have turned more towards the 'human' focus of the concept, the original definition in the Australian context referred mainly to the system configuration which consisted of an electronic blackboard (a Macintosh computer, using specifically developed 'blackboard' software -'Electronic Classroom') (Crago, 1992), linked using a PSTN telephone line via a modem to a computer/modem at the remote site. The classroom 'voice' link was provided through a second phone line fitted with a loudspeaker phone system. The 'paper' or notes link was provided by a fax machine, which in most schools 'shared' a phone line in the school office, or alternated with the 'blackboard' link. Whilst other more integrated systems, such as the IBM based OPTEL system were also considered, in the Australian context these were cost prohibitive. Many schools today continue to use the audiographic system as their primary distance delivery mechanism, with recurrent costs met through a central Department fund. Associated with this original project were a number of management, professional development and teaching and learning considerations which continue to inform current projects and practices as we learn more about the needs of remote learners and as technological capabilities continue to expand.

The Organisation: Clusters

Originally groups of schools in the same or close geographical proximity were grouped together. These groups - or clusters - are now an integral management component of technology-based teaching and learning developments and meet on a regular basis to share planning days and work on collaborative projects. In 1997 there are 19 clusters supporting 84 schools with, 675 students taught by 52 teachers in 61 subjects.

The schools are responsible for the design and delivery of the curriculum material and resources students use in their courses, with the central or State administration funding the initiatives. This emphasis on Statewide coordination has led to considerable cost benefits through centrally coordinated sharing and development of expertise within the clusters. For example, the implementation of technology has been on a Statewide basis with all schools having a similar configuration, thus avoiding many of the issues of non-standardisation. Some would argue, and rightly so, that there are some compromises with standardisation, such as limitations of the creativity which often characterise projects with a larger degree of freedom. However, paralleling the broader implementation of the standard formats and systems has been ongoing exploration and research into the newer technologies and alternate approaches and environments, in various parts of the State.

The Technologies

A consequence of technological development and ongoing research, original technology configurations continue to be upgraded, replaced andlor supplemented by peripherals such as scanners, digital cameras, CD ROMs, sound and video cards and cameras and videoconferencing. Hand-in-hand with these improvements to Telematics have been software improvements to 'Electronic Classroom' especially designed for use in the Victorian system (Ellis, A., Debreceny, R., Crago, R., 1996). 'Electronic Classroom' is the software used for Telematics, an Australian program developed by a programmer to suit the needs of Victorian teachers and students, written specifically for Macintosh computers. It allows computers at several locations to communicate with each other as a substitute blackboard.

With the world wide focus on exploration of the potential of the Internet and its resources for teaching and learning in the global environment, Victorian schools too have been and are becoming more deeply involved in exploration of this tool. As an example, in 1995 a group of Telematics schools teaching German trialed the use of the Internet as a teaching and learning tool. These teachers and students found many advantages in using email and Internet. Teachers reported improved learning outcomes for LOTE students - one of the outcomes they experienced was that the learning was set in a more realistic setting with a real reason for communicating in the target language. Usmg email students and teachers reported greater access to their peers in remote locations. All students said they had improved their skills in Information Technology and Telecommunications. Some teachers and students searched the Internet looking for links to German sites and making cultural connections for project-based work requirements.

Another advance in technology has pointed the way for schools to use even more advanced technology for teaching and learning. This further step was facilitated with the recent introduction of digital telephone services in rural Victoria, and the way was opened for school trials with videoconferencing over ISDN lines.

Teaching Strategies and Professional Development

Whilst the various dimensions of teaching and learning with technology continue to expand our knowledge and understanding of the differences and similarities in human requirements and needs in learning 'beyond the physical classroom' there is also a real need to disseminate and share the experiences of those involved in these explorations and developments (Dwyer, 1994). Thus the forms of organisational management and professional development form an integral component of project development.

At the cluster level, teachers in clusters work as a team, supporting each other with ideas and strategies which work for them within their cluster culture, encouraging each other at group days and professional development days in the cluster.

Example of professional development for teachers using telecommunications technology

On a State level, each year a Statewide training conference is held at which teachers display their experiences as team leaders and activity facilitators, passing on to others new to the approaches, strategies for best practice, and experiencing hands on practice with the technology and contact with peers which lead to networks of teachers supporting each other. New technology and new ideas in the field are presented in a cooperative informal atmosphere and valuable networking has resulted which is continued throughout the year and across cluster boundaries (Cerbasi, 1997). URL http://www.wimmera.net.au/edenhope/Telematics/Debit.html

One of the growing areas of need in professional development and on-going sharing relates to the Internet. Although it continues to be an increasing force in the educational life of students and teachers, ideas on how to use this electronic tool need to be exchanged and built on by all teachers. The mechanisms of cluster organisation and accompanying state professional development support these endeavours.

Schools have begun to use discussion groups for remote or electronic conferencing and gradually, as more schools access the Internet and the per hour cost of access to the Internet decreases, teachers are seeing the benefits of using the Internet and telecommunications generally as a teaching and learning tool. The impetus for change thus continues to progress exponentially.

As technological developments are realized there seems to be a natural trend for teachers experienced in Telematics and distance teaching to encompass the new developments with more ease than their classroom based counterparts (Marghitta 1994). Similarly, it might be suggested that teachers with such experience in their professional skills are demonstrating a more discerning approach to the characteristics of the newer technologies and a richer understanding of the fundamental changes taking place in the nature of teaching and learning with, and through, technology. Many teachers who have taught remotely, using Telematics are appreciating the capacity to *see* their students with full videoconferencing and have reported that this sophisticated, yet in many ways simple, development has facilitated a greater 'esprit de corps' in the class than was possible with the less holistically visually oriented audiographics system. On a contrasting note however, some have proposed a question for exploration in noting that the 'video component can, at times detract from the task at hand' - and this may be related to subject, discipline and individual taste. One teacher of English Literature said it was quite important to be able to see all participants in discussions and made sure that the cameras were positioned so that the students were visible.

Even with the more holistic views of videoconferencing however, experienced teachers continue to report the need for different types of interaction, ranging from face to face to the use of full video and simple audio (Daunt,1994). Particular days have been planned by schools and clusters, in which all students meet face-to-face, travelling the eighty kilometres in order to get to know each other better, before classes commence, or in the early days of courses.

It is not only the teachers who are mindful of the need for different 'human' approaches too. Many classes have adopted a procedure whereby a few minutes is devoted to social discussion and chit-chat at the beginning of each on-line session, regardless of the technology (ie both with audiographics and videoconferencing). These strategies have been used by Telematics teachers for a number of years as an important part of the socialising of the distance education class and to allow the teacher to get to know his or her students. Building personal relationships using technology is like creating a virtual classroom.

Towards a more holistic approach.

Until 1995 audiographics/Telematics was the predominant electronic means for teaching students in these remote schools. The Department of Education commenced trials of desktop videoconferencing in clusters when this technology became economically and technically viable. In 1995 the first cluster of schools was provided with videoconferencing facilities to trial distance teaching for delivery of curriculum. The introduction of videoconferencing was dependent on rural schools being able to receive digital telephone services - ISDN capacity being available in only some country areas. One of our major telecommunications providers, Telstra, is ensuring that all country exchanges in Victoria have this capacity to service country districts.

Videoconferencing: a Case for the present: a Case for the future.

Videoconferencing is currently being used on several levels throughout the state. The trialing of videoconferencing had several aims. In summary it aimed to explore the possible applications of the technology to assist in:

- enhancing curriculum delivery and student access to a comprehensive curriculum across the State
- sharing particular curriculum between sites - along the lines of master lessons/discussions/ lectures -for example between Science & Technology Centres Tertiary/ industry presenters and target schools.
- sharing access to visiting presenters, both for administration and curriculum.
- sharing special programs eg, Gifted children, disadvantaged students
- trialing links with Technical and Further Education Institutions (TAFE) for access to dual recognition programs
- trialing links with institutes of higher education and universities for professional development and delivery of accredited courses
- linking geographically dispersed teacher network members
- linking Victorian administrative networks in regions - School Principals, Working Parties
- trialing links with the Department's headquarters in the centre of Melbourne (the capital city of Victoria)
- linking sites for teacher professional development (EkinSmyth, 1995)

Let me now briefly provide a context for the aims of the trials by explaining a little about the focus and structure of technology related developments within the Victorian Department of School Education. The Department of Education has a particular division, Learning Technology Projects, whose brief it is to initiate, develop and manage technology-based projects across the schools sector within the state.

The division is responsible for overseeing projects such as the Telematics Project (Arms 1996), the exploration of the Internet and for videoconferencing, an interactive satellite network and a group of model schools called Navigator Schools, URL http://www.dse.vic.gov.au/navigato.htm.

A group of Secondary Schools has been designated as Science & Technology Centres. URL http//wwwdse.vic.gov.au/stcdesc.htm. Their mandate is to promote the teaching and learning of Science and Technology in schools Statewide.

Teaching and learning using technology is also the focus of the seven Navigator Schools. They have been set up to model exemplary teaching and learning and provide models for practicing teachers. Teachers and principals can participate in practicums and seminars where they attend sessions teaching them to plan and manage technology needs in their schools. Other sessions use counterpart training and workshadowing whereby participants work with Navigator School teachers on a 1:1 basis.

Videoconferencing then is one of many initiatives which the Department of Education promotes as part of its School Programs Division. Videoconferencing can be integrated into SOFNet - the Statewide interactive satellite network, also maintained by Learning Technology Projects. All schools in the state have been provided with satellite receiving equipment - for curriculum delivery and training for teachers through programs which are transmitted from studios in Melbourne.

SOFWeb is the Department of Education's Home Page on the Internet. This site is an extensive educational resource pointing to useful information for teachers and students. It promotes collaborative learning in such projects as the Global Classroom Project, (Coppinger&Hocking, 1995) I* EARN-a showcase for student's work, listing home pages for Victorian Schools on the Web, amassing case studies of leading practice in the use of Learning Technologies indexed to Key Learning Areas, reviews and research of Learning Technologies, and is a site where many Department of Education policy documents, guides and tender information is found. Discussion groups and conferences are being developed, the Virtual Lounge, Parents in Cyberspace and many other features and links to the Internet are accessed through this page. URL http://www.dse.vic.gov.au

In the not-to-distant future interoperablility of videoconferencing (especially desktop videoconferencing) and the Internet is envisaged, however currently it remains an issue to be resolved. As this technology is refined and simplified and becomes cheaper more schools will be able to afford videoconferencing as a part of their entry to the Internet. Multipointing - connecting more than two sites - is expensive at this stage, but it is anticipated that this too will become more affordable as more schools take up desktop videoconferencing.

Some preliminary data and findings.

A year into the trials it has been possible to witness the development of a number of levels of consideration.

There now exists a pool of teachers who have begun to develop their own strategies to address the teaching and learning needs of this environment. On a more practical level, some teachers focused on the physical characteristics of the teaching spaces, such as making a study of how everyone set up their room, light sources, location of table and chairs, some became aware of the need for choosing clothes and graphics to best highlight the light, colour and transmission possibilities to make the images more meaningful to the viewers.

Others focused on the use they made of the medium as a means of networking with colleagues in their field of interest within the cluster of schools and the ease with which they could contact experts in their field.

Of course, others focused more directly on the cognitive and social demands of teaching via the mechanism. As much of the trialing to date has focused on Year 12 - the final year of Secondary education in Victoria - teachers worked closely with their students in discovering

- how they were acclimatising to videoconferencing,
- how they used all the features of the technology,
- how the administrative back up worked in each of the schools in which their students were situated,
- how well their students coped with learning in this mode - which reflected in their examination results

Perhaps a few vignettes and anecdotal observations from the teachers will serve to demonstrate some of the considerations which are now being generated by this project

A question which is often asked of the teachers is how they can be sure that the work the students presented for marking was really their own work - how could the teacher authenticate each students' work?

> *One teacher noted that for this aspect of the extended classroom to work it is important to get to knowyour students early in the school year so that you know what to expect from them. All work was submitted on-line, so the students were exhibiting their technology skills and having ownership of their contribution. Also, paying visits to the remote students and sometimes actually teachingirom the remote site allowed the teacher to understand the constraints under which the remote students worked Also, students at the teacher's base school were able to appreciate the conditions under which their remote peers learnt.*

Not everyone finds the full videoconferencing facilities appropriate.

> *One teacher who has used an audiographic system since its introduction into the Victorian Education system, found that he and the students were more comfortable using an electronic whiteboard for teaching and learning rather than using collaborative computing via videoconferencing His subject was Accounting and he found that the teacher and students all had greater facility with manipulation of figures this way. The students at each location still saw the students and teacher on the screen but the actual computing was done on the electronic whiteboard. In sessions where there was mainly discussion and collaborative work was being done on assignments or projects, all features of the videoconferencing were used, for instance when a video of the Stock Exchange working was shown.*

Alternately according to an English literature teacher:

> *For Literature discussions you need to see the students all the time . "I use the videoconferencing 100% of my teaching time with these students. "*

Others have expressed similar likes:

> *"I think videoconferencing is far superior to Telematics and the students like learning this way. "*
>
> *"I have used both systems andfound there was greater clarity of picture with the room system and it had more features to offer as a tool. There was a better picture from the students on the desktop system as seen at Wangaratta than at Wodonga The kids f ind it FAR, FAR superior to the old system. It makes them feel part of the class."*

Teacher organisation and management has also drawn comment

> *" Videoconferencing has led to a marked improvement in delivery of curriculum. Students are more enthusiastic and curriculum delivery more efficient. It is good for teacher meetings; saves travel time. "*
>
> *"Professionally an excellent experience."*

And fnally as an example of the activities being undertaken in bringing expertise beyond the school and town into the classroom(s)

> *Students from a secondary school, Manangatang, 450 kms from Melbourne, were able to link into Courtroom 4 of the Melbourne Magistrate's Court to view a mock courtcase and afterwards discuss points of law and general information with all the courtroom personnel.*

> *In another situation, a Year 12 class in the country requested a speaker on one of their VCE English texts. A teacher from Melbourne fulfilled this role, addressing the students on the text, then discussing it with them.*

As a general comment it has been observed that these schools and teachers are developing a wealth of experience in teaching using electronic technology and are using these strategies in videoconferencing for collaborative computing, adding videos, digital images, using snippets from CD ROMS or slides as natural parts of their lessons.

To the Future

Teaching and learning using telecommunications technology in all its diversity is an important part of the future of education. The Internet is being explored by classroom teachers throughout the world as a means of teaching. In a changing world, the learning environment is gradually changing as educators see the enhanced possibilities which telecommunications has to make a quantum leap into the future. It may not be too excessive to claim that the very nature of teaching and learning, and the fundamental assumptions of each, will change drastically in the near future (if not in the already present!). These teachers in Victoria who have the experience of using Telematics and now videoconferencing to teach students in remote locations are well poised to begin adapting their curriculum to this new world where distance is simply a mindset.

The WWW from the educational point of view

The Internet has experienced a fast growing expansion to an information network, especially after the appearance of the WWW with its interactive graphic interfaces.
Today it is widely used by Internet service providers, diverse commercial and non-commercial services, schools and businesses in education and vocational training, and private users. Although the Internet as well as the WWW were in their beginning mainly used by universities and research institutions, they were originally not designed to support educational use. Their main use is information exchange and retrieval. Though the WWW represents a pool of up-to-date information that one may want to use to prepare presentations and learning material, it is not well equipped for preparing didactically sound material and presentations. In the following we point out some weaknesses of the WWW from the administrative point of view and for didactic criteria:

- Links are not administrated in such a way that links to documents which change their address can be updated automatically.
- Another consequence of the lack of link administration is the impossibility of determining which documents point to a shown document. (This causes specific didactic problems that will be discussed later.)
- There exists no overview of the outgoing links embedded in the document, unless the author specifically creates one with the help of HTML-frames.
- Only text oriented material with few possibilities for graphical interaction is available. Other material is time consuming to develop.
- There is no comfortable way to change material during a lesson.

While there are some genuine solutions for the administration of globally networked hypermedia documents which elimininate some of these deficiencies, most of the documents on the WWW are only available with the limitations already mentioned above [Andrews95] [Duval95].
To solve these problems, we propose that the WWW be integrated into an originally didactically motivated basic representation. This integration causes better management and more flexible preparation. In the following we focus on management. Our application scenario is a computer-integrated classroom based on [Hoppe93]. It has the following features:

- central interactive presentation by means of an electronic blackboard [Stefik87] [Elrod92];
- workstations for students networked among themselves and with the blackboard;
- functions to distribute "electronic worksheets" and other multimedia material;
- interfaces for intelligent monitoring of the student's work (with local feedback as well as feedback to the moderator);
- co-operation on the basis of synchronized applications;

Abbildung 1: **The authoring environment**
At the left-hand side are the buttons with which the links (arrow symbol) and the nodes (document symbol) can be generated. In the center there is an example of a Didactic Network. In the upper section are the editing helps and in the upper-left corner an overview of the whole graph.

A discussion of the intelligent run-time components can be found in [Hoppe95]. The starting point of the following considerations is a special authoring environment for the computer-integrated classroom. Basically, it supports teacher presentations of multimedia learning material on the electronic blackboard. The approach is to represent the curriculum as a graph with typed links and nodes called Didactic Network. Links represent a transition between presentation frames including certain didactic functions. The nodes contain the presentation frame where the type indicates the associated delivery medium. Compared with WWW-documents, the Didactic Networks produce additional information. This additional information, which offers a better context, includes the node type and the link type of the predecessors and successors. This paper offers a solution for integrating external WWW-documents into Didactic Networks to achieve better management and use of the WWW for didactic purposes. To do this, we have to distinguish the functions of the authoring system and the presentation environment.

Didactic Networks

The authoring environment (figure 1) supports the creation of a lecture concept or curriculum as a Didactic Network.
A Didactic Network is a directed graph. An "entrance node" (or root node) is required which should not be the successor of any other node. The nodes are typed and are coupled to certain methods. The type of node indicates the presentation medium which will be invoked for showing the

BEST COPY AVAILABLE

node's information during the authoring and the presentation phase. The following frame types are predefined: ***Active Text Frames, Audio Frames, Picture Frames, Graphic Frames, Program Frames, General Frames***[Baloian95]. Common methods such as ***add content, remove content*** and ***open***, are attached to frames and invoke the corresponding tool.

The links are labelled with didactic functions. There are no restrictions concerning the node types which can be connected. The following set of labelled links are available: ***exemplified by, explained by, introduces to, refined by, summarized by***. These links primarily focus on the didactic cause of a transition between nodes, not on the relation among the nodes' content. They serve as didactic support during the presentation.

The explicit management of links simplifies the determination of the incoming and outgoing links for each node.

The use of a graph as a representation of a curriculum simplifies its modelling because different aspects can be represented simultaneously. Firstly, because the graph defines a causality among units, the sequential structure of the lesson can be automatically derived. Therefore, it is possible to determine at any moment which nodes represent the basis for another one.

Secondly, due to the abstraction of the lesson content through the use of nodes it is possible to have an overview of the curriculum which enables the author to deal with more complex curriculum representations. Such complex curricula can be the result of additions and modifications made during a certain period of time. These complex representations facilitate and make further lessons more flexible because of the number of contained units.

Thirdly, the links labelled with didactic functions can motivate reflections about the adequacy of the structure being constructed and its accommodation to the teaching needs.

For the solution presented here we see following advantages:

- Nodes represent an abstraction of their content with the help of mnemonic naming. This supports the clear representation of the lesson.
- The overview eases the change between material and units even if the connection is transitive over several nodes.
- The nodes are typed according to their content media type and can be used to invoke the appropriate viewer or tools directly. Therefore, they support the presentation phase.
- Links define a partial order among the nodes (predecessor-successor) and, therefore, for the scheduling of the lesson content.
- Because graphs can be traversed in many different ways, there is a flexibility in defining the final shape of the curriculum during the presentation itself.
- The links are labelled. This information can be used for defining the border conditions of the presentation.
- The didactic functions support the reflection of the lecture's concept.

The authoring of a lesson is supported by an authoring system which is based on the hypermedia authoring tool SEPIA [Streitz92].

The presentation of Didactic Networks in the classroom

The presentation of a lesson is accomplished by navigation through the corresponding Didactic Network. The multimedia material that is invoked when a node is visited is presented on the electronic blackboard by the Lesson Manager (compare Abb.2). For each node, its predecessors and successors are presented with three elements each. An icon representing the node's type, a label with the link type which connects both, and a button with the name of the neighbouring node. These buttons can be used to change the actual location in the net.

During the presentation the teacher should be able to inspect the whole network to show an overview of the lesson and to jump swiftly from one node to another that is not directly linked. To do this, the teacher invokes a window in which the whole net is shown. The already-visited and still-not-visited nodes are distinguished with different colors. The nodes of this graph are sensitive so any node can be visited by clicking on it.

Expansion of the Didactic Networks to include WWW-nodes

The approach is to support the integration of WWW-nodes as part of the authoring system. WWW material is integrated into lessons by incorporating it as a new node type in the authoring environment. Therefore, all advantages concerning management functions are inherited by the new node type. Their use is similar to the other one's use and improves the handling of WWW material during the preparation phase.

The content of a WWW-node during the preparation is an URL address. When the node is invoked (during presentation or by checking its content during the authoring phase) the HTML-viewer is called and the current content of the page is shown.

The principal reason to include only the URL address and not the entire document is that the presenter may be interested in seeing the current data stored at this address which has perhaps changed since the previous preparation step. Normally, this is an intended situation for topical information like news or weather reports.

For easier management, the author can request from the system a list of all the links that a certain page may contain and select one of them. Afterwards, a new WWW-node with that URL which will be connected to the network as a successor node of the current node can be generated automatically .

Technically, the HTML-viewer is controlled by the Lesson Manager (see Pict. 2) The implementation of this control is made by a DDE interface. It mediates the communication between the Nestcape API and the Lesson Manager.

Based on this control, WWW-documents can be integrated to the presentation environment. If a WWW-node is invoked during the presentation, the HTML-viewer is started. Through its API the viewer receives the URL which should be loaded. In communication between the HTML-viewer and the Lesson Manager is Netscape the server and the Manager the client.

Expanded presentation functions

The integration of WWW-nodes into the presentation environment enhances the management functions for didactic purposes during a lesson. It solves the following problems:

- In big WWW-documents, it is not easy to get an overview of all the links that point to other documents.

  A standard WWW-document that is not prepared for didactic purposes will not serve as a guide to further information. Though an overview of contained links is not offered, it is necessary because of their unstructured distribution in a document. The presentation environment changes this situation by adding prepared guiding links between documents.

- The search for the "origin of information" may not be possible.

  To go to the "origin of information" is also possible with the aid of the presentation environment.

- Pages are often too big and extensive scrolling may be necessary.

  Scrolling for searching links that are located in a very different position in a document could be avoided by using an additional link to the presentation environment. This improves the orientation for the presenter as well as for the listeners.

Perhaps similar advantages could be achieved by the development of a specialized HTML-viewer instead of an embedding system. This could eliminate some problems by having the document shown in an adequate format and by the intelligent processing of the document. The problem is however that the construction and up-to-date keeping of an HTML-viewer would demand too much work and would be soon out of date.

Our solution is an external control of an existing HTML-viewer. The inclusion of WWW-nodes achieves the following goals:

Integration of WWW-pages in such a manner that they are included swiftly as integral parts of a lesson or presentation which may include WWW and non-WWW material. The aim of the integration of WWW-nodes is to enhance the presentation possiblities and to extend the information

At the right hand side the Lesson Manager is depicted. One can see at the top the predecessors and under them the successors of the node being currently visited. According to the node's content there are sometimes at the bottom right buttons to control the interaction with the learners (send learning material and start student's program). An enter for each neighbouring node consists of a symbol for the node's type, an abbreviation of the link's type and a labelled button to invoke the node. The bigger window at the left shows the content of the current node which in this example consists of a WWW-node with page containing Java-applets.

pool for selecting the material. The integration of WWW-nodes to a presentation environment also includes more flexibility to combine HTML-documents and other tools, especially multi-media material.

Dealing with HTML-nodes during the presentation

About the authoring style and common practice of the documents existing in the WWW we can say that in general, the links of the HTML pages point to pages which display related content or details of the anchored text or image. Thus, the link structure is more content oriented. In contrast, the link structure in Didactic Networks has didactic purposes. The overlapping of the WWW link structure with that of the Didactic Network arises with the inclusion of WWW-pages in the presentation which may complicate the navigation.

At first glance, disabling the HTML links may seem a good solution, but this limits the possibility of searching for new information during the presentation. In our opiniion, a better solution is to keep this overlapping structure and regard a WWW-node as one entry to the WWW during the lesson.

The problems resulting from the overlapping and, therefore, confusing link structures could also be minimized by including all the WWW-pages that one would like to show in the Didactic Network

BEST COPY AVAILABLE

as a WWW-node when possible and avoiding the use of the WWW-page links.

Commentaries and Perspectives

With the inclusion of WWW-pages in the Didactic Networks we give the teacher or presenter the possibility of selecting presentation material and information from the widest and fastest expanding pool of multi-media information with free access. It seems that in the near future serious attempts to develop computer based teaching or presentation systems should consider the WWW as one of the main information and presentation material providers.

This system now allows a way of organizing WWW-pages in such a manner that:

- It is possible to organize a lesson with WWW and non-WWW material.
- It is possible to link WWW pages that were originally not connected without having to change the content (links) of any of them.
- It is possible to organize a coherent lesson with WWW-documents maintaining the overview of the structure even in a complex situation.

The labelled links not only support the authoring process of a lesson, but also serve to support the teacher during the presentation.

The approach described above will be expanded in the following way: Under certain conditions, it may be possible for the teacher to ask the system to give suggestions about the next node to visit. This decision-taking engine should be parameterized with the teacher's profile for the current lesson, for example preferred teaching style. An inductive approach would choose to visit the neighbouring nodes pointed with "exemplified by", while a deductive approach would prefer those pointed with "explained by" or "refined by". Also the teaching history (visited nodes) would be considered.

Electronic Performance Support Systems and Information on Demand

Philip Barker

Abstract: Electronic performance support has become an important technique for improving skills and enhancing knowledge acquisition. This paper discusses the rational underlying the use of this technique, identifies some basic principles and illustrates their use through a case study involving 'information on demand' as a necessary requirement for efficient and effective problem solving.

1. Introduction

We live in an era of unprecedented change and uncertainty. Increasingly, this has meant that organisations have had to compete more aggressively for the basic resources that are needed in order to survive in a rapidly changing world. They have thus had to maintain their competitivity through various types of internal reorganisation and the development of new products and/or services. Furthermore, in order to sustain their growth, most organisations have had to put into place a variety of different mechanisms to maintain existing client bases and, at the same time, develop new markets for their products and services.

Undoubtedly, within most organisations the demands of a dynamically changing environment has necessitated the realisation of many internal programmes of re-adjustment. Inherent in these programmes of organisational change is the need for a continual re-assessment of the nature, structure and function of the various departments and work groups that make up any given organisation. Invariably, re-structuring and reorganisation implies changing job roles. This, in turn, implies the need for post-holders within an organisation to acquire new skills and the knowledge needed to fulfil different job functions.

Within many organisations, situations of the type described above have created a requirement for new approaches for the provision of in-house learning and training opportunities for staff. Invariably, these involve the use of powerful, interactive multimedia computer-based systems that embed a wide range of courseware products that are designed to meet the training needs of the organisation. Computer-based training (CBT) was one of the first techniques to emerge from the use of this type of equipment [Dean and Whitlock, 1988]. However, many other approaches are also feasible. Some typical examples of the more recent educational paradigms that are now being used to facilitate in-house staff development include: 'on-the-job' training, 'education on demand' and 'just-in-time' training. Along with many other important techniques for information handling and provision, these paradigms form the basic foundations for the development of sophisticated job support tools. The development of these computer-based tools for use as performance aids within organisations has led to the creation of a new area of endeavour referred to as *'electronic performance support'* [Gery, 1991; Banerji, 1995].

There is considerable evidence to show that when performance support techniques are introduced into an organisation they can be used to facilitate significant improvements in the work-place performance of individuals, work-groups and other organisational units. Usually, these improvements manifest themselves in terms of efficiency gains, cost reductions and enhancements in the quality of the products and services involved. The cumulative effect on the organisation itself is therefore seen in terms of enhanced productivity and greater competitivity in the market place.

Because of the widespread and growing importance of the role of performance support within organisations, this paper discusses some of the current developments taking place in this area. It commences by outlining the basic nature of electronic performance support. It then goes on to describe a simple *'four-layer model'* and an associated set of *'Principles of Performance Support'* that can be used to help design electronic performance support systems. A simple case study is then presented which describes the development of facilities to provide 'information on demand', that is, it illustrates the role of mobile computing equipment as a mechanism for providing global access to information held on a remote in-house intranet facility. The paper concludes with a short discussion of some of the future possibilities for the use of these techniques.

2. What is Performance Support?

All organisations engage in activities that are designed to further their (sometimes conflicting) goals and objectives. Goals and objectives are realised through the successful completion of 'job sequences' and 'tasks'. As we shall discuss in the following section, each of these types of activity, in turn, often involve various aspects of problem solving.

Within any given target organisation, it is convenient to identify 'task domains' in which people are involved. A task domain (or work area) provides a context and environment for the execution of those tasks that are necessary for the fulfilment or organisational goals. Associated with any given task domain are: (1) a set of relevant and appropriate skill levels; and (2) acceptable levels of prior knowledge of the domain tasks. Expert performance in a task domain will therefore usually depend upon meeting each of these criteria - as well as being able to utilise (in an effective way) any performance aids that are available.

Obviously, people who are involved in task execution within a given domain will be subject to their own innate physical and cognitive limitations - for example, how rapidly they can respond to a stimulus, how much they can remember and how quickly they can perform a mathematical computation. Therefore, bearing in mind such limitations, the area of performance support is concerned with the design and creation of tools, techniques and mechanisms that will improve human performance beyond the limits set by innate natural ability. A performance support system can thus be used to develop augmented levels of achievement within particular task domains. As was mentioned in the previous section, computer-based systems are now increasingly being used as performance support tools because of the powerful multimedia, hypermedia and communications facilities that they make available.

Within the work that we have been undertaking in this area, we have regarded an electronic performance support system (EPSS) as a computer-based interactive guidance and information support facility that is integrated into the normal working environment of an individual or work-group [Barker and Banerji, 1995]. In our current research into 'multimedia performance support systems' we have been particularly interested in the various ways in which multimedia and hypermedia techniques can be used to improve the performance of task operatives within particular application domains. This has involved trying to identify a model for the role of multimedia techniques within the context of EPSS [Hudson, 1997].

The importance of multimedia and hypermedia within electronic performance support systems is reflected in the definition given by McGraw who defines an EPSS as 'an integration of artificial intelligence (AI) technologies, hypermedia and CBT' [McGraw, 1994]. Her view of an EPSS is therefore based on a system 'whose components include embedded training, hypermedia help, AI-based coaches and an adaptable, model-based user interface'. Although embedded training is usually an essential aspect of performance support, it is important to realise that an EPSS facility differs from a CBT system in a number of important ways. These differences are discussed in detail in [Varnadoe and Barron, 1994].

In her recent research, Gery identifies three basic type of EPSS facility which she refers to as: intrinsic, extrinsic and external [Gery, 1995]. Within an intrinsic system the support that is provided is so inextricably integrated with the software design that it is basically seen as the software itself. In an extrinsic support system, aiding is integrated with the software, but it is not part of the primary display; such support can be turned on and off and must be actively invoked. Finally, external support (which may or may not be computer-mediated) is not actually integrated with the work context; the performer must therefore break context and access something that is clearly different from being supported while situated in meaningful work. The way in which these three different types of EPSS facility relate to each other is illustrated in the case study that is presented later in the paper.

3. Basic Principles of Performance Support

As a result of their exploratory research into the design of electronic performance support systems, Banerji and Barker have formulated a basic 'four layer' *model for EPSS* [Banerji, 1995; Barker, 1995]. This model was intended to act as an orientation facility which could be used to draw a designer's attention to the important design issues that need to be addressed during the design of an EPSS. The four layers involved in Banerji's model were: (1) the end-user interface; (2) the generic toolsets; (3) the application specific toolsets; and (4) the application domain itself.

At the topmost level, the human-computer interface is a critical component of the overall system since it provides users with a mechanism for accessing and controlling the facilities available at lower levels. Text-based command-line interfaces, graphical user interfaces and the selection of appropriate metaphors are therefore important design considerations at this level. As is reflected in levels 2 and 3, we make extensive use of toolset metaphors within the end-user interfaces of the EPSS facilities that we design.

The generic toolset level of the model provides a wide range of tools for use within the EPSS. At this level a designer must select that combination of toolsets that is most appropriate for the target application. The toolsets available include: help systems; documentation support (both paper-based and electronic); text retrieval; intelligent agents; tutoring and CBT facilities; end-user modelling facilities; simulation and surrogation tools; communication tools; and so on. As was suggested above, within this level of the model the system designer can 'pick and choose' the types of tool that are best suited for the target EPSS depending upon the functions it is expected to perform. The way in which some of the more commonly used generic toolsets map across onto the required EPSS functions has been described in detail in [Stevens and Stevens, 1995].

Level 3 of the EPSS design model deals with the application orientated toolsets. These are used to perform various tasks within the application domain. The tools in this category may already exist within the application domain or they may need to be specifically built for the target system. The target application itself, for which the EPSS is being built, lies at the lowest level of the model (Level 4). Obviously, the EPSS that is finally produced must integrate smoothly, effectively and seamlessly into this level.

As well as formulating a primitive architectural model for EPSS production, Barker and Banerji have also derived a set of ten basic *'Principles of Performance Support'* and a series of guidelines that could be used to facilitate the practical application of the principles in any given EPSS design situation. Obviously, when designing an EPSS facility, it is important to realise that in any given situation, not all of the ten principles will necessarily apply. It is therefore necessary to identify that subset which is the most relevant and applicable to the situation being considered. The way in which this is done is illustrated by means of the case study that is presented in the following section.

4. A Case Study - Information on Demand

This section of the paper presents a case study that illustrates the way in which performance support techniques can be used to improve an individual's problem solving ability through the provision of easier access to information as a result of the use of mobile computing equipment. The case study is organised into three parts: the first gives a brief description of the scenario; the second identifies and presents a statement of the principles used; and the third gives an outline of the solution itself.

The scenario is as follows: an academic who frequently travels away from his university needs to keep in touch with his research colleagues. His travel takes him to a variety of national and international destinations. While he is away from his campus, he also needs to be able to process his electronic mail and gain access to both his personal files of information and the university's corporate data files. The material that is to be accessed exists on an in-house intranet facility and on various Internet and World-Wide Web servers that are located at his university base.

The three principles of performance support used in this study are referred to by Banerji and Barker as Principle 1 (P1), Principle 3 (P3) and Principle 4 (P4) [Banerji, 1995; Barker, 1995]. The first of these principles states: specify and prioritise the critical areas of under-performance within the application domain and then identify appropriate strategies to improve performance. The next important principle (P3) recommends: identify relevant generic and application-oriented tools and processes which will provide on-the-job support and improve task performance. The final principle that was used in this study (P4) suggests: attempt to identify and, if possible, eliminate all unnecessary information blockages and constrictions within an organisation or a work environment.

The final solution to the problems identified in the scenario above was based on a practical realisation of the three principles just discussed and involved the use of mobile computing equipment [Barker, 1996]. The relationship between the mobile computing equipment and the fixed facilities located at the lecturer's university base is illustrated schematically in [Fig. 1].

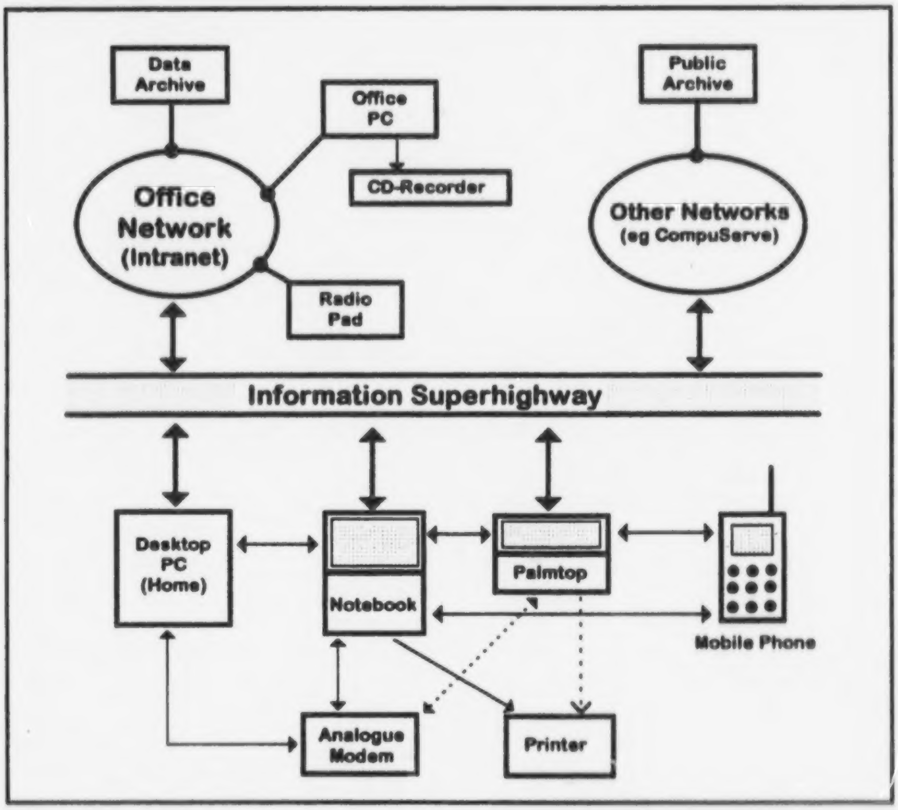

Figure 1: Basic technology to support information on demand.

As can be seen from [Fig. 1], three basic transportable items of equipment were required: (1) a PC-based notebook computer running Microsoft's Windows (Version 3.1) that was equipped with a PCMCIA fax/modem card; (2) a hand-held palmtop computer (a Psion 3a) to which could be attached a serial fax/modem link; and (3) a digital mobile phone (a Nokia 2110) that could be connected either to the palmtop computer or to the notebook. The palmtop and notebook computer could also be connected together to facilitate local data exchange. As well as using the Windows 'Terminal' software, the notebook computer also had a Netscape web browser installed on it. The communications software on the palmtop was a simple VT100 emulator. Although the palmtop could not use Netscape, it was able to use the 'Lynx' text-based browser.

BEST COPY AVAILABLE

Although the combination of equipment described above cannot be guaranteed to provide 100% availability of information, it does substantially improve the academic's access to his remote resources. Provided that there is service coverage in the area where he is working, the digital phone can be used to provide 'roaming' access. If connection via the digital cellular network is not possible then the analogue phone system can be used to provide reliable access to his remote information - provided a suitable telephone socket is available.

Bearing in mind what has been said above, we are now trying to develop information handling strategies that will reduce costs and minimise the inconvenience caused by not having 100% roaming access to information. The solution that we are proposing involves the use of portable mobile digital libraries (that are published on optical disc) and the implementation of `virtual office' systems using the World-Wide Web. Details of this work are presented elsewhere [Barker, 1996; Beacham, 1997].

5. Conclusion

The principles underlying electronic performance support provide a powerful framework to facilitate the design and development of job support aids and productivity tools. Such performance enhancers can be used to enable individuals, work groups and organisations to overcome many of the problems that they face as a consequence of natural human limitations and the constraints that they impose. Within this paper a simple model for EPSS development has been proposed along with an accompanying set of basic principles of performance support. The way in which these principles are used in order to solve a `performance' problem has been illustrated by means of a short case study involving the provision of facilities to support `information on demand'. Our future work into EPSS methods is aimed at trying to identify further fundamental principles of performance support based upon the use of multimedia, hypermedia and distributed systems technologies.

Abstract: The paper discusses theoretical and methodological problems of software evaluation in Higher Education. It criticizes the commonly used approach in product evaluation using numerically weighted lists of criteria. On this basis, an alternative method with qualitative weighting is presented. The European Academic Software Award held in Klagenfurt/Austria in 1996 (EASA '96) serves as an example of the practical implementation of this method, whose outcome is reported at the end of the paper.

1. Motivation

The evaluation of interactive media becomes more and more important: on the one hand because of the growing offer of software from which good products have to be chosen, on the other hand in order to promote software quality and to set quality standards. In the domain of academic software, the EASA was created with these considerations in mind.

The aim of EASA is to promote the development and use of software in research and higher education. There are two main aspects to this aim, reflected by the definition of "academic" software as either software *for use in* higher education and research, that is, educational software, but also tools for teaching, learning, and research, or as software developed *in* higher education and research. The award is intended both to make software producers and distributors aware of innovative ideas and programs developed in the academic world and to point out to the academic audience good examples of technology-enhanced teaching and learning.

The original focus of EASA being the promotion of new developments excluded the use of certain evaluation approaches, like, for example, a quasi-experimental design (comparison of reference groups by pre- and post-testing). At the first EASA (Heidelberg, 1994), the evaluation was done instead by expert groups using lists of criteria.

2. Evaluation with checklists

In checklists, the features that are considered necessary and/or desirable in the product that is to be evaluated (the evaluand) are listed, and the product is rated for each feature. This method has a number of advantages: It is

- *cheap*: one expert, one licence of the program and the suitable hardware configuration are in principle sufficient to evaluate the software and fill in the checklist.
- *easy to organize*: the software need not be assessed in a situation of real use (classroom), evaluation can be assigned to a specialized (and centralized) group or institution removed from the context of use.
- *at first view, methodically "clean"*: by going through the same, often voluminous checklists in each examination, the method appears to be objective.

However, this method is insufficient for different reasons:

- The practice of establishing lists of criteria and of working through them in the evaluation procedure does not avoid the problem of weighting the different features to come to a final conclusion: "No software is perfect. Every item has strengths and weaknesses. It is the evaluator's job to identify those virtues and defects and then decide which outweigh the others. - It is a judgement call." ([Doll 1987], p. 58). But it is exactly this "judgement call" that has to be methodically clean, and this is the methodological problem the present paper focuses on.
- Another problem lies in the assumption that the usefulness of educational software can be assessed in a context-free judgement. Often, however, it is not the product (piece of software) itself but the innovative use that is made of it that guarantees the positive learning effect. For this reason, future EASA evaluations will include case studies and shift the focus of the assessment from the product to the learning situation.

3. The Logic of Evaluation

Basically, "evaluation is the determination of a thing's value" ([Worthen and Sanders 1987], p. 22), or, as Scriven ([Scriven 1991a], p. 1) puts it: "Evaluation is the process of determining the merit, worth and value of things, and evaluations are the products of that process."

This definition implies that in the center of every evaluation is the formulation and assignment of a value judgement. In this sense the logic of evaluation are different from other disciplines (e.g. social research).

- Formulation of value criteria: First, those criteria that the evaluand has to satisfy in order to count as valuable or good are selected and defined.
- Formulation of standards: For each criterion, a standard or norm has to be established. Only if the evaluand comes up to this standard, it is considered as satisfying the criterion.
- Measurement and comparison (analysis): The evaluand is analysed and measured on each criterion and compared to the predefined standards.
- Value judgement (synthesis): In this last and most difficult stage of evaluation, the individual results of measurement and comparison have to be integrated into a single value judgement.

Each of these steps or stages gives rise to certain problems:

- *Formulation of criteria*: Which criteria should be chosen? What importance (weight) should be given to each criterion for an overall assessment? Note that this is mostly a theoretical question whose answer needs a thorough analysis of the evaluand. The attempt to arrive at a complete list of criteria by putting together all existing lists (as done, for educational software, by [Thomé 1989], who collected 324 individual criteria from which she compiled a "Long Checklist for Educational Software" with 221 criteria) does not solve the problem, because it does not guarantee neither that the criteria are independent of each other nor that they are really of equal importance.

- *Formulation of standards*: This implies that criteria have to be operationalized, which has not yet been done for the majority of the criteria usually applied to educational software. For example, how should "interactivity" be measured? Based on the analysis of the evaluand (in our case: of theoretical assumptions about academic software) we can distinguish three main levels of standards:

- Level 1 = Requirements or needs (necessitata): These must be satisfied in any case if the evaluand should be included in the further evaluation procedure (k.o. criteria). They are essential criteria that every evaluand must have or fulfill, for example: a certain educational software cannot be used if it does not run with the existing hardware.
- Level 2 = wishes or desiderata: These are functions and features that are not mandatory but useful. They increase the value of the evaluand and are important for the final value judgement (e.g ranking). They have to be defined and weighted in a way that mirrors the evaluation goal. (For examples cf. the list of criteria used in the EASA Competition in [Tab. 1])

  Two commonly made mistakes are: (a) Too many and too detailed criteria, whose number and collective weight inundate the evaluation process and complicate the synthesis needed for the final value judgement. (b) A bias towards certain features results from criteria that "overlap" (= are not independent of each other).
- Level 3 = ideals: Although they can hardly be reached, they provide an important perspective by pointing to ways in which the evaluand could be further improved. This is especially important for formative evaluation, where the evaluand is still under development. Most of the EASA criteria can also be used for program improvement, and actually this is one of the motives of this award: to raise the quality of academic software.

- *Measurement and comparison*: This stage depends on the previous operationalization of criteria. Where this is - as in the case of interactive media - still under way, no generally approved, tested and normed scales are in use. Instead of objective measurement, we therefore had to rely on dialogue and intensive discussion between jurors and authors and among the jurors themselves. Contrary to an objectivist point of view, we do not consider this to be a shortcoming. In expert groups a certain element of subjectivism helps to integrate different opinions. Often the qualitative assessment is a preliminary stage for the establishment of an accepted standard that finally can lead to a quantitative evaluation procedure. We doubt, however, that this will ever be the case with educational software.

- *Value judgement*: The integration of individually assessed criteria into one value judgement implies a prior definition of the role or weight of each criterion. Such a definition has to be based on the theoretical assumptions that have to guide the evaluation procedure. At last year's Ed-Media Conference, we proposed a detailed theoretical framework that can be used as a heuristic model for such an assessment ([Baumgartner and Payr 1996a]). In this paper, we will therefore concentrate on the methodological difficulties. Let us first compare two methods commonly used for the weighting of criteria in product evaluations - numerical vs. qualitative weight and sum.

4. Methods of Weighting

4.1 Numerical Weight and Sum (NWS)

This method is frequently applied and can take different forms. The general form is called multi-attribute utility analysis ([Scriven 1991b], p. 380f.): 1) The relevance (weight) of each criterion is set using a scale from e.g. 1-3, 1-5 or 1-10. 2) The evaluand is rated for each criterion. 3) Rating multiplied by the weight gives the result for each criterion, results are added up for each evaluand. 4) The final result is a single number for each evaluand. The evaluands can be ordered by this number (ranking), the one with the highest score being the "winner".

This method has a number of intrinsic problems:

a) By attributing and adding numerical values, this method assumes a linear scale of utility for all criteria. But this assumption is clearly wrong! At the moment there is no normed, tested, standardized and agreed linear scale for the quality of educational (or academic) software and it is doubtful if there will ever be one. As it stands, the different components or dimensions must not be added up to a single final number.

b) The multiplication used for weighting also presupposes a metrical scale where a zero value makes empirical sense, which is not the case with many criteria. It could maybe make sense-, for example, with the criterion of "documentation" (from "no documentation at all" to "all features are documented"), but any other question like "is the documentation adequate, clear and useful?" can only be answered on an ordinal scale (like: "sufficient - good - excellent") that allows ranking, but not calculation.

4.2 Qualitative Weight and Sum (QWS)

This alternative method overcomes the methodological difficulties of the numerical approach and consists of three main steps:

1st step: Constructing the list of criteria
As in the NWS method a list of criteria is established and weighted. The crucial difference is that QWS is not based on the assumption of an interval or ratio scale. In order to prevent the possible confusion with numeric operations that are only legitimate for linear scales, Scriven ([Scriven1991b], p. 294) recommends the use of symbols for the weights. Frequently used symbols are: E = essential, * = very valuable, # = valuable, + = marginally valuable, and 0 = zero.

2nd step: Weighting of criteria
The weight of a criterion determines the range of values that can be used to measure an evaluand's performance. For a criterion weighted #, for example, the evaluand can only be judged #, +, or 0, but not *.

Three rules help to execute complex product evaluations, e.g. evaluations with many evaluands and many different components or dimensions:

1) *Elimination of evaluands:* An evaluand that does not satisfy a criterion considered essential (E) is eliminated. In our case, such a criterion could be, for example, if a software crashes. Such a criterion can already reduce considerably the number of evaluands. But the process of elimination is not always as easy as the example suggests. Essential criteria often are not "all or none" criteria, but establish a certain minimum standard of performance. For example, response time of a software must not be longer than a certain limit (set by psychological factors), but inside this limit the variation of response time does not make a substantial, qualitative difference.
2) *Elimination of 0-criteria*: Every criterion that gets the weight 0 in the weighting process can be eliminated - it is judged irrelevant.
   The remaining evaluands (after applying rule 1) are now evaluated by attributing a value for each remaining criterion (after applying rule 2) up to the maximum weight. If a juror does not feel sure or has any doubts he/she can put a value in brackets, so that this criterion for this evaluand is marked for further analysis or comparison.
3) *Elimination of criteria with uniform results*: Criteria where all evaluands have reached the same level can be eliminated from further consideration, based on the assumption that all evaluands are more or less equal in this regard and that the criterion therefore does not contribute any distinctions.

3rd step: Ranking
Counting the different symbols given to each evaluand results in three numbers for each evaluand - the number of *, of # and of +. The evaluands can now be ordered (ranked) according to these numbers.

This ordered list can either be used for grading, e.g. for cutting off a certain proportion of evaluands either on top or on bottom of the list, or it can be the basis for determining a "winner" and a ranking of results. For a definitive ranking, however, results have to be analysed more closely. There is no doubt that an evaluand with 3*, 4# and 2+ is better than one with only 2*, 5# and 2+, but it is not clear whether it is better than one with 2* and 7#. It may be necessary to analyse and compare these two candidates more closely.

It may also be necessary, in case of unclear results, to proceed to a second round of weighting. The method of QWS is not only complex, but also has this disadvantage of not offering a clear decision algorithm. Sometimes it has to be applied several times and the evaluations have to be redone in the light of previous results.

5. QWS Applied to EASA

The method applied in the final evaluation round of the EASA was a variety of QWS ([Baumgartner and Payr, 1996b]). It departed from the general method as outlined above mainly by not using the E symbol or essential criteria. The reason for this was that the programs admitted to the final stage of the competition had already been tested and pre-selected, so that they could safely be assumed to satisfy a certain minimum standard for the criteria that played a role here (they were, of course, functional and virus-free, but the pre-selection had also looked into aspects of educational use, language, design and innovation). The shortlisted projects (35 out of 157 submissions) were invited to the final event, together with 20 jurors drawn from the jurors' body established in the pre-selection round and 5 additional student jurors. The authors set up their software in an exhibition-style setting. The evaluation process took two days, starting with an introductory session where the "rules of the game" were established, and ending with a plenary session where the final decisions on the award winners were endorsed.

5.1. Weighting of Criteria

A list of 12 criteria ([see Tab. 1]) was proposed to the jurors. The jurors attributed the value of *(very important), # (important, relevant) or + (additional, less important) to each criterion. This specific expert group considered all 12 criteria at least "important", but most of them "very important" (criteria 3, 8 and 11 had #, the rest *). So the jurors gave themselves, for most criteria, the broadest possible range of values to attribute in the following evaluation round.

5.2. Evaluation

For the evaluation, jurors worked in five sub-groups. Each of these sub-groups had to evaluate seven programs. They had a whole day for examining the programs and the documentations and for requesting additional information from the software authors. The jurors filled in their evaluation form for each software individually and then discussed it in their sub-group to come to a single group evaluation. Only this group result was taken into account for the subsequent ranking.

5.3. Ranking and Discussion of Results

The next day, the evaluation results were presented to the plenary session of jurors in the form of tables where not only the integrated results (the number of * etc. for each software) were made visible, but also the result for each criterion, including bracketed symbols and cases where jurors considered a criterion not to be applicable. Moreover, these tables were arranged and presented under different aspects, like submission category (department projects, student projects, and commercial projects), country of origin, and discipline. This documentation was necessary as a basis for the discussion of the results. Certain aspects had to be analysed before coming to a decision:

- Are the results consistent, i.e. have the groups applied comparable standards when attributing values for each criterion, or are one group's results constantly lower or higher than the rest?
- Is an overall good result, but without any highlights, i.e. twelve #, but no * - preferable to a software with some outstanding features, but also with some weaknesses - i.e. six * and six +?
- How many awards should be given away, and in which categories? For example, if the best program of a certain award category comes very late in the overall ranking, is it still good enough to get an award, or should this award be left out?

- Does the resulting list of award winners represent the different disciplines, countries, submission categories etc. well enough?

EASA '96 Evaluation Criteria

1. Correctness: Is the subject material accurate and up-to-date? (For tools:) Is the program functional?
2. Relevance: Does the software correspond to real user needs? Is the contents relevant for teaching and learning in the subject area?
3. Coverage: Is the subject material sufficiently covered? Does the software cover an important part of the subject area? (For tools:) Is the range of functionality appropriate?
4. Interaction: Is the software highly interactive? Does the software encourage active/exploratory learning? Does the software create and maintain learner motivation and interest? (For tools: not applicable)
5. Learning: Is the material well structured and organised in order to support the learning process? Are learning objectives defined and can they be attained? (For tools: not applicable)
6. Usability: Is the software appropriate for the target group it addresses? Can the software actually and easily be used in research, teaching and learning? Does the software run on current students'/universities' computers?
7. Navigation: Can users always see clearly where they are in the program and what actions/functions are available? Does the software always show its current staturs, mode? Are reactions of the program to user actions clear and appropriate?
8. Documentation: Is online help available? Are manuals, tutorials etc. available? Is the documentation clear and useful for the target group?
9. Interface: Are contents and functions well organised on the screen, easy to learn and used, and well presented? Does the software follow the known standards of interface design? Does the software satisfy ergonomic requirements?
10. Use of computer: Does the software support activities, forms of teaching and learning that are not or not easily feasible otherwise? Does the software make adequate use of the medium?
11. Adaptability: Can the software be easily updated and adapted to new contents and teaching/learning requirements? Is the software portable to other European curricula and languages?
12. Innovation: Does the software contribute new and interesting aspects to educational computing and multimedia? (For tools: ... to computing?)

Table 1: Evaluation Criteria used for EASA '96

In the case of EASA, no single "winner" had to be found, so that the method was used for a process of apportioning: a group of award winners had to be cut off from the rest of the finalists (who, in their turn, were already considered "winners" of some sort, having reached the final stage of the competition).

The plenary discussion had, in this case, to take the role of the re-analysis and comparison of evaluands, simply because of the limited time frame.

The results showed a rather clear "top group" that was defined as the award winning group without much further discussion. It only had to be completed with some programs that were promoted from "lower down" in the list, the submission category turning out to be the decisive factor: these additional award winners were student projects, which jurors did not expect to offer the same level of performance and quality as department projects and commercial software.

6. Conclusions

We started out criticizing checklists as a method of evaluation for interactive media, went on to present alternatives and reported the practical experience with the qualitative weight and sum (QWS) method as used by an expert group in the EASA '96.

Applying this method of product evaluation to the EASA can serve as a good illustration of the necessity to come to terms with both theory and practice of evaluation in any specific setting. While theory can clarify the respective merits and shortcomings of different evaluation methods and formulates the critical questions that guide evaluation design, practice sets up inevitable limits of time and cost to any evaluation. What we hope to have shown is that by

- clearly defining the evaluation task at hand
- following the logic of evaluation and
- taking into account the practical limitations

it is possible to design evaluation settings that are theoretically grounded, practically feasible and adequate for their specific purpose and goal.

As there exist plans to broaden the scope of the European Academic Software Award to include not only software products, but also case studies and experiences in the innovative use of software in higher education, EASA will be progressively leaving the field of product evaluation. With these new pedagogic goals in the award, other methods of evaluation will have to be found and tested. So we can look forward to the next EASA which will take place in the U.K. in 1998 (see [http://www.york.ac.uk/inst/ctipsych/easa/]), both for interesting submissions and for new insights into their evaluation.

Distributed Learning by Distributed Doing

Benjamin Bell, Robert Raoul Meyer
{benjamin.bell, rrm11}@columbia.edu
Center for Intelligent Tools in Education
Teachers College, Columbia University USA

Abstract: The convergence of several technological trends holds great promise for distributed learning. Faster throughput, better data compression, and reductions in the cost of multimedia desktop computers and peripheral hardware have brought the prospects for geographically distributed instruction within the reach of many institutions and their students. Colleges and universities have thus begun exploring the difficult questions surrounding the design and content of distributed courses. In a survey reported in this paper, we identified three patterns in how higher education was leveraging computer-supported distributed learning: as a resource space, as a discussion space, and as a collaboration space. To determine what influences the outcome of a DL design effort, and to begin articulating how software tools might make such efforts easier, we developed a sample online module and made it available to graduate students. After presenting the results of that trial, we offer recommendations for fostering faculty and student participation in the distributed learning enterprise.

Goals of the Project

Colleges and universities are increasingly cognizant of the importance of extending the reach of their academic activities beyond the campus. Emerging technologies such as desktop videoconferencing and realtime, multimedia Web documents suggest ways of enriching the remote experience in ways that can begin to replace some of what is lost when classes convene virtually rather than physically. Without an established methodology for creating DL instructional material, though, individual faculty must synthesize their own schemes for producing material. Because some of these efforts are likely to result in interesting and powerful approaches, one goal of this research was to survey and evaluate a representative sampling of courses offered using internet technologies (partially or exclusively). Another consequence of the absence of a systematic approach to DL design is that most faculty do not have the time or expertise to augment their courses with technology-supported instruction. A second goal of the study was therefore to construct a sample DL module and apply that experience in articulating how faculty can more readily participate in this enterprise.

Distributed Learning Survey

As a prelude to our course development experiment, we conducted an informal survey of roughly one hundred sites on the Web that offered undergraduate or graduate instruction. From these, we selected twenty four that demonstrated the range of techniques, domains, and effectiveness we encountered among the larger sampling. For each of these, we applied a qualitative instrument to evaluate the materials along several dimensions, including the role of the DL activities in the overall course, the appropriateness of the technologies employed, and a subjective, qualitative rating. The course reviews were posted on the Web in tabular form [Fig. 1]. Since the purpose of the survey was to inform our subsequent design activities, we were interested in what the results had to say with respect to the following two questions: what makes online materials effective?; which technologies are needed for conducting meaningful online instruction?

What makes online instruction effective?

Results from the survey suggest some of the ways in which traditional instruction can be adapted to a distributed format. Our aim is not to discuss specific pedagogies[1], but to develop a set of capacities shown to make important contributions to DL instruction. The twenty-four courses analyzed in the survey were evaluated using a qualitative instrument consisting of six dimensions:

1. Intended Audience - who would be taking the course
2. Course Content - what materials were available online
3. Technologies Used
4. Role of Online Materials - how the online components of the course were used to enhance instruction
5. Appropriateness of Online Materials - how suited the materials were for the technologies employed
6. Level of interactivity - the extent to which communication and interaction were accommodated

	This is a well designed site dedicated to computational science. The discipline itself is rather	

Figure 1: Segment of Online Course Survey

Most courses in the survey adhered to a traditional style of instruction, in which the instructor specifies some material to be covered and then administers some sort of evaluative exercise, usually a paper or a test. In general we found that the courses which best took advantage of the medium were those associated with the most interactivity, meaning they provided the greatest opportunity for communication among class participants and between student and instructor. Almost all the courses surveyed took advantage of email, but far fewer afforded any real time communication using the internet.

The most highly-rated distance learning courses in the survey shared three attributes. First, they feature access to resources that are comprehensive (in the context of a particular course), as well as thoughtful instructions and clearly defined expectations for the students. These sites incorporate assignment schedules or similar planning milestones, so that students are held responsible for accomplishing specific tasks by specific deadlines. This seems to capture some of the essence of an on-site class in that students have a common basis for discussion of a selected topic, but offers students some control over their own learning processes. Second, these courses are enriched with communication. Among the more highly-rated courses, we observed real time communication elements, through discussion forums, chat rooms, or desktop videoconferencing. Through the use of such technologies, these courses gain some of the immediacy and accountability of on-site classroom interactions. Third, the highly-rated courses accommodated collaborative interchange among students. Some collaboration was observed using the same tools employed for communication, namely discussion forums, chats, and conferencing. In some cases these technologies were augmented by special collaborative software that created a shared work space, such as a whiteboard or shared window that participants could annotate and modify.

We also observed some less effective uses of distance learning. The majority of these were limited adaptations of existing classes in which the instructor posted notes and assignments but made little or no attempt to address the communicative aspects of instruction. This approach is acceptable when the materials are intended to augment a class that physically convenes, but some of the courseware we encountered in this category was presented as being more self-contained than was actually the case. Such sites fail to present the student with anything to do other than view information; they do not include any task that the student is expected to accomplish. In addition to those courses that do not sufficiently leverage the possibilities of internet-enhanced instruction, we encountered some that are just poorly conceived, lacking a coherent navigational path, confusing students, and making it difficult to understand just what students are expected to learn.

Which technologies are needed for conducting meaningful online instruction?

The best technologies for online instruction are the appropriate ones. The internet can deliver information in multiple media, from simple text to full motion video. From the survey, it appears that certain technologies offer promise for distance instruction when employed in particular ways. Email was used in almost all courses for communication between students and instructors and among students. The most effective way to hold group discussions seemed to be a threaded forum, (*e.g.*, a newsgroup). The more highly-rated courses in the survey incorporated these features directly into their web pages. Chat rooms were used as well, and were especially suited for collaborative concept development and brainstorming. Email seemed to yield better results for this purpose, though, because its non real-time nature allowed participants to more carefully construct their messages. A few made use of simulations, though these were held in files for students to download rather than being available directly within the students' browsing software. Desktop videoconferencing did not appear to be widely used, either because of the time constraints it puts on interaction (conferees must be at a computer at a specified time) or because current low-cost conferencing technologies provide poor image quality and frame rates. However, the two most highly-rated courses surveyed did include some type of real-time communication between student and instructor, either via videoconferencing or chat rooms.

Survey Results: Summary

Accompanying the absence of a standard methodology for DL course development is the reality that no single technology can reproduce the critical elements of the conventional classroom experience. Online courses are therefore often implemented as a cluster of materials supported by disparate technologies. Moreover, technology is a double-edged sword, introducing challenges that can be viewed as barriers, opportunities, or both. Primary among the opportunities is of course the ability to instantly disseminate class-related materials to a global audience at minimal cost. A principal barrier, on the other hand, is the absence of the richly communicative context of face-to-face classroom interaction. The potential for students to collaborate and share their findings is both a barrier (because of the steps required to implement the appropriate connections) and an opportunity (because technology liberates collaborators from familiar constraints such as place, time, and Federal Express). We therefore offer the following three recommendations based on our findings:

- **Resource Space**: DL instruction should include instant global access to all materials relevant to the course, in the most appropriate medium (or media), and compatible with all appropriate platforms. Any collection of materials made available to students should be accompanied by a plan or map that learners can use to guide their exploration.
- **Discussion Space**: DL instruction should accommodate the exchange of ideas, data, and information, between student and instructor, among students, and with appropriate experts and scholars in the field, and should support all modes of communication (text, audio, and video, both synchronous and asynchronous).
- **Collaboration Space**: DL instruction should provide channels for students to engage in joint research, design, development, and distribution of class-related project work, in whatever formats or media are suitable for the domain of study.

Distributed Learning Design

The second phase of our research was to construct an exemplar DL module that would observe in general the three recommendations arising from our survey. The module encapsulates one class meeting of a core course in the design of educational technology at Teachers College, Columbia University, and was tested by students enrolled in a summer session of the course in 1996. We established a framework for our design that defines three functions that the online instruction must serve: resource space, discussion space, and collaboration space.

The resource space

Students enrolled in the course could obtain a range of class materials via the Web. Class descriptions, a syllabus, and assignments were posted to the class web site. Additionally, those readings that were available online were referenced from within the syllabus. Finally, numerous sources of related information were offered via a "related links" section common to most web sites.

The discussion space

The course used in this study included a strong emphasis on discussion, and so an effort was made to preserve that emphasis for the online session. Two types of forums were explored in our investigation: threaded discussion (newsgroups), and real-time, text-based conversation (chat rooms). Both forums were accessible to students using simply a standard web browser.

The collaboration space

Students worked in teams of four or five members to develop a distributed learning "mini-module" to teach a subset of material offered in the course. Collaborative interchange was supported via the discussion groups, shared web pages, and desktop conferencing. At the conclusion of the DL session, students were asked to post their reactions to a discussion group dedicated to this purpose.

WHY USE AUTHORING TOOLS IN THE CLASSROOM?

Allowing students to create their own multimedia projects helps to fulfill a number of needs that we consider especially important in an educational setting. Below are some of the theories that authoring environments speak to, with some links to sites that exemplify or display student projects.

CONSTRUCTIVIST ENVIRONMENT

environment

A collection of articles on constructivism and education.

An example of how constructivism is governing the use of authoring to teach mathematics.

An example of a constructivist approach to history.

Figure 2: Opening screen from student-designed distance learning module

Results

Constructing an exemplar DL module provided useful insights into the strengths and deficiencies of online distance instruction. In general the students' responses to the online components of the course were positive. However, although students commented that the discussion forums in particular were useful, there was a consensus that they could not and should not supplant the classroom experience. Each of five project teams created a learning module to teach a topic related to instructional design of educational technology (which was the focus of the course). The topics selected by the projects were Communities of Practice, Exploration Learning, Anchored Instruction, Assessment of Constructivist Artifacts, and Hypermedia Browsing [Fig. 2]. In the course of designing the projects, collaboration was observed in several forms:

- participants made use of the discussion groups to brainstorm and refine their preliminary ideas, schedule meetings, and report progress.
- individual teams maintained their emerging designs on a web server, so that members could share work incrementally and also to invite comment from the class at large.
- teams conducted text, audio, or video interviews via the internet with scholars appropriate to that team's topic area, and posted the results of those interviews as part of their evolving learning modules [Fig. 3].

Interview with Expert: John Cleave

On Topic of Anchored Instruction

Question #1: What is anchored instruction?
Question #2: What is a good example of web-based anchored instruction?
Question #3: What is the feasibility of moving to an anchored instructional framework
Question #4: How can faculty evaluate students' performances?
Question #5: What would be the ideal percentage mix of different types of instruction?
Question #6: Do we rename "teachers"?

Figure 3: Expert interview included in student-designed distance learning module

These modules also pointed out the shortcomings of the web as a medium for collaboration. Although the web provided for sharing the product of the collaboration, much of the actual design of the modules was carried out in face-to-face interactions. Students did not view the web as capable of providing both a space in which to create artifacts and a tool for commenting on and altering what was being created. The use of collaborative tools such as ComMentor [Röscheisen, Mogensen, & Winograd 1996] and CaMILE [Shabo, Guzdial, & Stasko 1996] that give students the ability to comment on artifacts within web pages offer promising approaches.

Discussion

Embedding a pedagogical model

Our survey yielded little in the way of distance instruction that observed some explicit pedagogy. The online courses relied overwhelmingly on two kinds of activity: individual exploration of static content, and email (or threaded forums like news) to talk about issues relevant to the class. Whatever instructional strategies might have been employed by those instructors in face-to-face class meetings did not find their way to the online complements to those courses.

We conceived of the class project work as a preliminary step toward embedding an explicit model into online instruction. Engaging students in the construction of DL modules is consistent with the notion of a cognitive apprenticeship [Collins, Brown, & Newman 1989]; students were expected to become instructional designers while working with others in the field of instructional design. Students engaged in creating instructional materials about their selected topic necessarily acquired new expertise in that topic and, equally importantly, were put in a situation where they could immediately apply their new skills and knowledge. The point was not to train students to create distance learning; that task simply served to anchor the exploration of the selected topic. Thus our approach also parallels quite closely both Goal-Based Scenarios [Schank, Fano, Bell, & Jona 1993/4] and Anchored Instruction [CTGV 1990], two models that prescribe an authentic task and an environment in which to pursue that task as a means for learning-by-doing instruction.

Our experience suggests the possibilities for distance instruction as a means for supporting or sustaining communities of practice [Lave & Wenger 1991]. Students in our sessions used telecommunication technologies to interact with experts in the field of instructional design. This use of technology to expand and introduce students to communities of practice is perhaps the most promising direction for future research and implementation given that one of the most important and overlooked aspects of university education is the enculturation that takes place in traditional university settings [Brown & Duguid 1996].

Deficiencies in the Design

The generally positive results from the study were realized despite one principal design flaw: the instructional module lacked any sort of unifying metaphor to assist navigation and to present the resources within some intuitive context. Some of the sites in our survey adopted spatial metaphors, for example, including a campus, mall, or village square. Specific resources could then be identified as "cafe", "library", "post office" and so on depending on the metaphor. Although students' reactions to and use of the DL materials were encouraging, the distance portion of the course was only one session (out of eight total). Students could therefore rely on in-class meetings to resolve any problems associated with the DL material or to simply get

BEST COPY AVAILABLE

acquainted. We made no attempt to analyze the extent to which our results could be applied more broadly, though the pedagogical leverage enjoyed by our goal-based approach is likely to be broadly applicable.

Conclusion and Future Work

In this paper we presented results from a survey we conducted of university-level distance instruction. Findings from this survey helped us define an approach to distance instruction that calls for three "spaces": resources, discussion, and collaboration. We introduced a sample distance learning session that was conducted as part of an on-site course in instructional design, and that was created with our survey findings in mind. Because one notable deficiency of the DL material we encountered was the lack of an explicit instructional approach, we created our sample DL module adopting a situated, goal-based pedagogy in constructing the activities.

Our experiences with online distance learning have suggested some positive aspects of online distance learning and have indicated some directions for future research and course development. Primarily we must conclude that successful distance learning must be firmly based in communication and be used to enhance more traditional student-instructor interaction. Online distance learning is effective to the degree that it creates and maintains learning communities which support knowledge construction. Current online distance learning courses are too instructor driven and lack the opportunities for communication and collaboration that support genuine learning [Slavin 1980]. The creation of more collaborative tools allowing students to create and refine knowledge artifacts online is encouraging [Harasim, Calvert, & Groeneboer 1996]. Web-based communications technologies will no doubt continue to evolve to support more real time communication and a more seamless interface between communication, collaborative space and collected resources [Harasim 1990]. Flexible tools that help course designers to organize their information and incorporate communication and collaborative learning thus need to be extended beyond the current model of an HTML template for didactic presentation, toward virtual communities of practice.

The Virtual Gallery: Exhibit Design as a Tool for Inquiry into Art, Artifact & Culture

Benjamin Bell, Evangelia Dimaraki

Teachers College, Columbia University, USA
{benjamin.bell, dimaraki}@columbia.edu

Mary K. Brown
The Dalton School, USA
Mary_K._Brown@dalton.org

Abstract: The study of a culture's artistic heritage can be a source of great instructional leverage, not only to convey principles of aesthetics and of the art itself, but also as an anchor for exploring related facets of a civilization's legacy, including, *e.g.*, its religion and mythology, political structures, and societal practices. This approach is explored in the VIRTUAL GALLERY DESIGN PROJECT. Our aim is to establish a framework for historical inquiry in which students become active participants in seeking and applying new knowledge. This paper introduces an explicit instructional framework that situates learning within an exhibit design context. A student in this leaning environment assumes the role of a museum curator, engaging in historical inquiry through the process of defining an organizing theme for the exhibition and by providing commentary that elucidates the exhibit. To illustrate a specific instance of this framework, we present a prototype application in which the task is to construct a special exhibit on Women of Greek Antiquity. The approach adopted in creating the software can be formalized as an explicit architecture that can subsequently be used as a design blueprint for a specialized authoring tool to support the creation of other versions of the Virtual Gallery Design software. We conclude with a discussion of how to realize this goal.

Current Practices in History Instruction

Although the Virtual Gallery framework is applicable to a wide range of disciplines, we are targeting history instruction in our initial application. In particular, we see three specific problems in history and social studies instruction. First, the current textbook-based teaching of history creates the illusion that history is "what happened in the past," rather than being a product of scholarly interpretation. Secondly, an over-reliance on the textbook makes the historical period under study unnecessarily remote to students and deprives them of opportunities to acquire a deeper understanding of past cultures by examining the richness and detail of actual evidence. Finally, an opportunity to educate students to view artifacts as sources of information is missed.

Traditional modes of teaching history that rely exclusively on secondary accounts necessarily obscure the dimension of history as an interpretive act. If students were immersed in an environment where they were *doing* history they could engage directly in interpretive work on the surviving, necessarily fragmentary evidence of the past. *Doing* history reveals that while history is not "objective fact", neither is it arbitrary storytelling. Rather, it is based on the disciplined study of objects and texts and on the application of historical knowledge created by previous scholars. In school learning there is, typically, an imbalance, that favors learning from text, over all other sources. As a result, most members of our society do not know how to approach objects and imagery as sources of information. Specifically in the study of the past, however, there has been a traditional distinction, carried over into school History, between the discipline of History dealing primarily with "written history" and the disciplines of Art History, Archeology, and Anthropology, which are concerned primarily with the study of objects. In our research we aim to include the interpretation of objects in the general enterprise of history [Pierce 1994], by leveraging the potential of new media for the study of objects [Allen & Sterman 1990].

Rationale

The combination of artifactual and textual evidence together with secondary source material allows the student to create a more comprehensive picture of culture. The Virtual Gallery Design Project is therefore intended to teach students how to synthesize, in the form of a gallery exhibition, a coherent presentation of some significant aspect of past culture.

The pedagogy adopted in the projects aims to situate learning within a context that allows the student to apply newly-encountered knowledge to a meaningful task. The basis for such a framework lies in two general principles of learning supported by current educational theory and research: (1) Goals play a central role in learning [Ng & Bereiter 1991; Schank 1994]; (2) The learning of new knowledge is facilitated when the knowledge can be applied in an authentic context. [Brown, Collins, & Duguid 1989; Whitehead 1929]. An emphasis on pursuing a specific goal may at first seem difficult to implement in the study of the past cultures. What does "doing" mean in the context of a lesson on Ancient Greece? The Goal-Based Scenario (GBS) framework [Schank, Fano, Bell, & Jona 1994] answers this question by calling for some meaningful task environment in which to embed the teaching of content. One answer to the question "for what task is knowledge of Ancient Greece required?" is the task of designing a museum exhibition. Therefore, a plausible role for the student to assume is, in this instance, "curator of Classical Antiquities" (or rather "apprentice curator").

The curator metaphor allows the integration of artifactual and textual evidence in a goal-directed inquiry, while shifting the focus toward the images that the culture itself has left for us. Engaging the students in a goal-directed inquiry leads them to actively compare objects; look for similarities and variation in theme, style, composition and context; seek links that connect the juxtaposed material [Spiro & Jehgn 1990]; use texts to contextualize the objects and elucidate the meaning of their representation; and integrate both the textual and artifactual evidence of the past. The intent is not to teach students to be curators, but to allow them to think like curatorial scholars. The process of assembling and reassembling objects into an exhibition which makes a visually substantiable statement engages the student in composing and applying knowledge of a culture's heritage. [Fantham et al. 1994; Pierce 1994; Morris 1995].

Women of Greek Antiquity: A Virtual Gallery Demonstration

The Virtual Gallery Design Project is a general framework within which we created a demonstration application called "Women of Greek Antiquity". This somewhat controversial topic serves as well in demonstrating some of the strengths of the pedagogy that we are proposing. Views about the role of women in Greek Antiquity differ between traditional scholarship and more recent scholarship, often coming from a Women's Studies perspective [Pomeroy 1975].

In the context of "school history", where Classical Greece is often treated as the basis of modern Western Culture, the roles and status of women in Ancient Greek society are only rarely and tangentially part of the curriculum. This offers a distorted picture of history that makes women relatively invisible and that encourages gender biases by students in their study of history as well as in their views of contemporary society.

Rather than debating what is the "correct historical content that we should cover in school", however, we propose instead to use the identified debate as an opportunity to introduce students to the way of thinking by which our knowledge of the past is created. Recent scholarship that has attempted to give equal weight to texts and art [Fantham et al. 1994] suggests a picture of the role of women in antiquity that is variable, complex, often contradictory, and sometimes bizarre, defying easy answers and categorization The richness of material and the lack of easy answers in the selected topic are precisely the attributes which make for the authenticity of the task; this is the kind of topic which practicing scholars regularly address in their work.

Description of the Program

The nature and context of the student's task

Curators creating a special exhibit are in a sense composing a visual essay. They the available body of knowledge as a tool to identify within such a broad, open topic of interest, as "Women of Greek Antiquity" a dimension that they can address with an exhibit [see Pandora 1995]. They actively look through the collections in their home museum (and from other museums) for objects that are instances of the chosen dimension. They research primary texts for passages that shed light on this dimension and enhance the meaning of specific objects. They develop a structure for the exhibit which in a sense corresponds to establishing and elaborating on a "thesis" derived from available evidence of the past and reflective of their expert judgment. Finally, they select and organize the objects in the gallery space so as to convey the point of the exhibit in a coherent and engaging way. The student using the Virtual Gallery Design program will be taking up the same task.

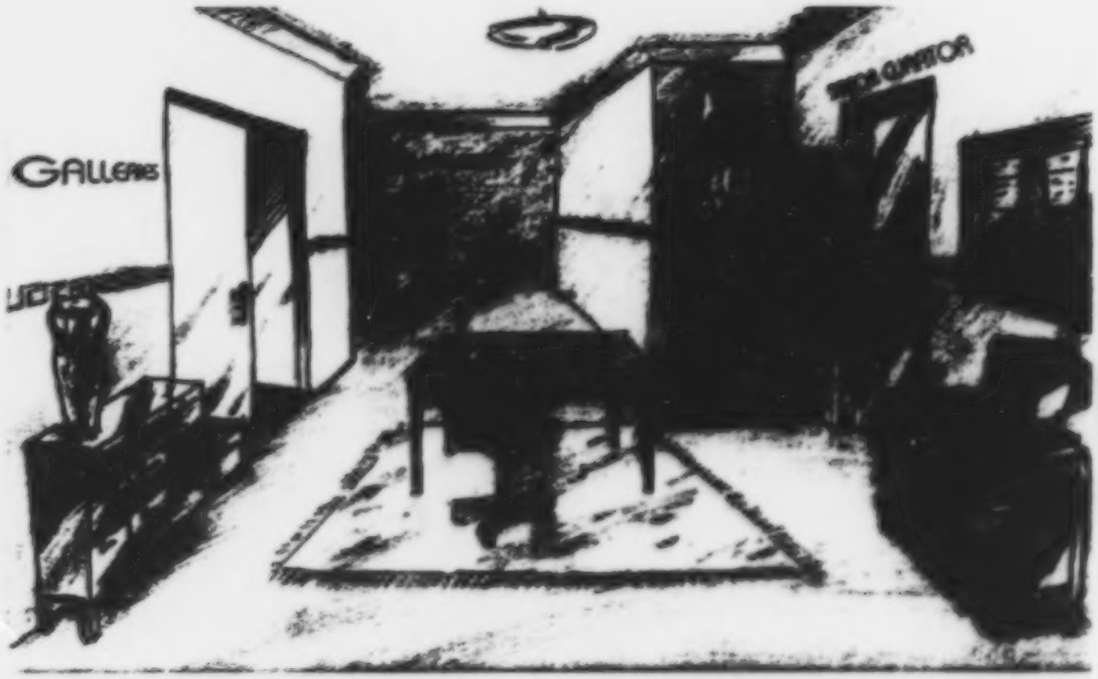

Figure 1: The Backstage Workrooms of the Museum Program Components

Immersing students in the task of constructing an exhibition is only one piece of a comprehensive learning environment. Supplying them with appropriate support resources is a second. The application provides the student with a collection of works of art , gallery spaces to populate and a virtual workspace, complete with a set of research tools to help the student in designing the exhibit. It also provides the student with expert guidance in the form of audio and video clips of a "senior curator".

Gallery space

The gallery space of the simulated museum contains the designated *special exhibit galleries*, initially empty and "closed to the public", that the student must populate with works of art. In a subsequent version we will include a ***Permanent Exhibition*** organized in the standard chronological way that will serve as a quick visual introduction to periods of Ancient Greek History and Greek Art and as a point of entry for the student who is not yet motivated to build an exhibit, but would like to browse through the program.

Research Tools

The research tools available to the student are organized around the metaphor of "backstage workrooms" in the museum [Fig. 1]. The *research desk* [Fig. 2] contains structured forms that help guide students' exploration of the works of art by prescribing a set of subtasks to be pursued: articulating an exhibit topic and structure, labeling the gallery spaces to reflect the selected topic and structure, grouping together objects and assigning them to parts of the exhibit. A structured notebook is provided for the student to record research notes and inferences as well as design ideas. Templates are provided to compose descriptive essays accompanying each object and "wall text" introducing the galleries to the visitors. The structure of the research room is intended to reinforce the idea of an exhibit as a "visual essay" and to guide the student in marshaling her arguments. It also scaffolds the student in successfully managing a complex task that might otherwise prove overwhelming.

List of Objects :
- Statuette of Athena
- Wedding Loutrophoros
- Funerary Loutrophoros
- Bacchic Skyphos
- Head of Athena
- Chios Kore
- Flying Nike

Figure 2: The Research Desk for the learner as "Apprentice Curator"

The searchable photo-archive catalog displays a picture of the object together with basic archival information and short curatorial notes. It is as a research tool that allows the students not only to browse the collection but to locate objects relevant to the topic that they are pursuing, through categorical searches by label, date, material, location found, origin, and curatorial note. The action of "ordering photos from the archives" serves as a metaphor for selecting an object for study.

The basement is where full size, high resolution images of the objects are displayed. It is the place where the student goes to browse and closely examine an object. The basement serves in focusing the student on studying individual works of art without the distraction caused by the presence of interface elements and text. Of course, the basement metaphor is also meant to evoke a sense of curiosity, important for exploration.

The gallery grid is a tool that allows the student to design the spatial layout of the exhibit, prior to "mounting it" (i.e., sending the objects to the gallery space). It presents a layout of the gallery in which the student can arrange objects by dragging them.

Expert Guidance

Expert support, in the form of advice and commentary, is designed to provide task guidance to the student. The "expert", in this program is a "Senior Curator of Classical Antiquities". The guide's role to advise the student on possible strategies to try next, or places in the program that might be useful to visit at the current point in the interaction. The "Senior Curator" initially appears on video to explain the student's mission. The description of the student's mission is available to the student throughout in written form through a bulletin board labeled "Notes from the senior curator".

The "Senior Curator" appears on video, subsequently, at the student's request. The student can "ask" the expert questions such as the following:

BEST COPY AVAILABLE

What is a Special Exhibit?
What exhibit structures are possible?
How do I study an object?
How do I choose objects for the exhibit?
How do I decide on my exhibit structure?
What should each room introduction include?
What should I write in an object description?
What should the exhibit introduction include?

The menu of questions that is available to the student in each interaction with the "Senior Curator" is context sensitive. Sound bites of the expert also accompany the student in her exploration of the basement, where appropriate, for example to direct the student's attention to an object or a part of an object that is particularly important; to relate a myth or fable to an object.

Subsequent versions will include additional expertise in the program in the form of videotaped interviews with curators, art historians, archeologists, anthropologists and historians. The content of these interviews will be indexed into brief segments according to the questions answered and raised by the remarks in that segment.

Content Material

The collection of content material will eventually include a collection of objects, texts, secondary sources and a stock of exemplar exhibit topics. The *collection of objects, complete with archival information* currently includes 60 objects of Ancient Greek Art selected to exemplify as exhaustively as possible the range of representations relevant to women. The collection includes painted vases, pedimental sculpture, relief sculpture and free standing statues in marble, bronze, and terra-cotta and repousse metal work. The program indexes these objects in ways that encourage students to make meaningful conceptual links among the material, in particular (1) by browsing the objects (we use the metaphor of "walking through the basement" of the museum); and (2) through a searchable "photo-archive catalog". In future versions we also plan to link each work of art in the collection with comparable objects.

The following content components although not yet implemented in the current version are part of our conception of the workspace as a structured task environment. *The body of selected excerpts of primary texts* will be indexed based on the objects to which they have relevance. The purpose of the collection of primary texts is to enhance the student's ability to study an object by helping her to identify elements of the representation (e.g., the identity of objects, human figures), to discover the meaning of a scene, or to notice a detail in the composition. Further, texts add to the broader context of interpretation offering insight into the ideas, conditions and concerns of the society that created the art. Finally, the texts may serve as quotes for the student's gallery texts.

A set of abridged general reference material on Ancient History and Art serves two purposes: as a quick overview of Greek History when needed; and for easy access to basic information that is instrumental to the task at hand. In this sense our reference material redefines the role of the traditional textbook, by turning it into a cognitive tool in the service of purposeful inquiry.

A set of exhibit design ideas accessible to the student through the "Curatorial Resources Cabinet" offer an alternative venue for approaching the task at hand. This venue provides the student with a number of exemplars demonstrating possible ways to structure an exhibit, according to accepted principles of exhibit design (chronological, geographical, by medium, thematic, etc.). The purpose of these examples is, first, to provide a more structured approach to the task for the students who desire it, thus avoiding the frustration of unstructured exploration, and, second, to serve as a resource for comparing, evaluating and refining ideas for all students.

Future Work

The Virtual Gallery Design Project helps a student to view the material remains of the past from a perspective that typically lies within the sole grasp of the scholar. With the Virtual Gallery Design application, middle-school and lower-level high-school students will be able to construct their own exhibitions around the topic "Women of Ancient Greece" thus developing and applying knowledge of History, Art History, and Archeology in authentic ways.

A broader aim of this research, however, is to develop a widely applicable paradigm that will facilitate the construction of other, related applications. The aim is to ultimately make the construction of other Virtual Gallery Design applications a task that demands knowledge of the target domain but requires little computer expertise. A specialized Virtual Gallery Builder tool will allow domain experts and instructional designers to readily create new instances of the Virtual Gallery. For instance, a "Decorative Arts of 18th Century Europe" Virtual Gallery could be created by adopting broadly similar architecture but replacing the Greek content in the original software with a new set of materials. This architecture, though, reaches beyond the study of material culture of the past. It could be used in a science and society curriculum, for example wherein the students create their own AIDS education exhibits for a virtual science museum; or a teacher developing a Peace Studies curriculum might used this tool to support students in constructing exhibits in tribute to victims of genocide. The specifics of what each such application might teach can vary widely; what all applications will share will be their underlying pedagogy.

Conclusion

The Virtual Gallery Design Project seeks to create a learning environment in which the task of exhibit design is used as a window into historical inquiry. This goal-based approach to instruction is particularly suited for the study of history and social studies because: (1) it brings the student into contact with both artifactual and written evidence, the two sources of information about the ancient past, and engages the student in thinking both with images and with text; (2) it creates a simulated task within which these primary sources can be authentically combined with more traditional aspects of teaching such as textbooks (used as cognitive tools) and direct instruction; and (3) it authentically incorporates the goal of synthesizing evidence into a coherent account or argument, presented both visually and in text, in the form of a completed exhibit. A study of the roles of women in antiquity is only one instance of a Virtual Gallery Design environment. Of greater significance is the more general approach to instruction that it demonstrates. The Virtual Gallery Design Project will yield an architecture that can guide the development of subsequent computer-based learning environments.

Wx-Brief: Aviation Forecasting as Earth Science Inquiry

Benjamin Bell, Heather Vaughn, Joshua Reibel
Institute for Learning Technologies, Columbia University, USA
{bell, heather_, joshr}@ilt.columbia.edu

Abstract: Data Analysis for Understanding Global Systems (DAUGS) is an instructional model under development that engages the learner in formulating predictions within a simulated task environment. Part of this research is the development of an exemplar application called *Wx-Brief.* [1] This simulation-based learn-by-doing environment teaches secondary science students about the causes and behaviors of atmospheric phenomena. A student using the software assumes the role of a weather briefer who must respond to pilot requests for weather conditions likely to prevail during a particular flight. In this paper we introduce Wx-Brief and include a sample interaction that illustrates some of the features of the application. We then explain the DAUGS model of which Wx-Brief is an instance. We conclude with a discussion of how our instructional approach may be applied in combining simulation with real-time information.

Wx-Brief: An Exemplar Application

We are developing an application, *Wx-Brief*, to both serve as an instance of a proposed instructional model, Data Analysis for Understanding Global Systems (DAUGS), and help guide its definition. The application was selected on the basis of its merit as a standalone research project and as a potentially important adjunct to current classroom practice.

Motivation

Study of atmospheric phenomena illustrates some of the limitations of traditional instruction. The factors influencing weather are numerous and complex, but conventional science classrooms offer little opportunity to explore these interrelated phenomena within some meaningful task environment. Predicting the weather, for instance (routinely employed by advocates of hands-on science), is a step toward in-situ inquiry, but demands only an understanding of how various instrument readings correspond to likely changes in weather patterns, without requiring a deeper understanding of the causes of such changes.

Description

Wx-Brief is a program aimed at addressing these difficulties. A learner using this software assumes the role of a forecaster who assists pilots in preflight planning by synthesizing a forecast tailored to the pilot's proposed flight path and departure time. In the course of preparing the weather briefing, the learner will develop an understanding of the forces governing weather patterns. Instruction in the Wx-Brief application will be organized as a set of modules, each focusing on a visible weather phenomenon that will serve to anchor inquiry into a related set of concepts. Our initial efforts are focused on developing an instructional module centered around thunderstorms; we will subsequently develop precipitation, wind and fog modules. In carrying out the task of providing pilots with pre-flight briefings, the learner will for each phenomenon acquire the skills involved in predicting it and explaining the conditions required for its formation, identifying it from observations and weather products, accounting for its present behavior, and projecting future behaviors. Each module thus represents an analog to a chapter or unit in traditional Earth Science classrooms [Tab. 1].

Interaction Synopsis

The software consists of three parts: the interface, which sets the context, presents the available resources, and maintains the results gathered by the student [Fig. 1]; a database of reports and maps relevant to each scenario; and expert guides (meteorologist and weather briefer) to answer questions likely to arise. In a typical interaction, the student is first presented with a weather briefing situation and then encouraged to analyze reports and maps in order to construct the requested briefing. The software guides the student's investigation into the connections and causal relationships among various weather phenomena. The student ultimately provides a summary of his or her findings in the form of a briefing to the pilot. Once the learner submits the briefing, he or she sees a briefing that an actual weather briefer prepared for the corresponding flight, and can then examine actual conditions that prevailed and how closely they matched those forecast. Differences between forecast and actual conditions then serve as focal points for continued inquiry.

---

[1] The title of the application comes from the telephone number adopted by convention by the regional Flight Service Stations providing pilot weather briefings, 800-Wx-Brief.

	Instructional Goals	**Target Concepts**	**Scenario**
Thunderstorm	predict it explain the conditions required for its formation identify it from observations and weather products account for its present behavior project future behaviors	water vapor, stability, condensation, cumulonimbus cloud, fronts, air masses, squall lines, hail, lightning, thunder	pilot requests outlook briefing for flight plan that could encounter severe systems.
Precipitation	predict it explain the conditions required for its formation identify it from observations and weather products account for its present behavior project future behaviors identify types of clouds relate weather to cloud types	water cycle (condensation, evaporation, precipitation), fronts, relative humidity, saturation, dew point	pilot requests routing that would remain clear of precipitation
Wind	predict it explain the conditions required for its formation identify it from observations and weather products account for its present behavior project future behaviors identify prevailing wind patterns in various regions associate wind with other phenomena	radiation, heat, temperature, pressure, absolute and relative humidity, Coriolis effect, convection, jet stream	pilot requests forecast turbulence along route of flight

Table 1: Initial modules comprising the Wx-Brief application

Example: Thunderstorm module

We use the Thunderstorm module to illustrate some of the interaction between user and system. The opening segment includes an introduction in which the Supervisor says, "Welcome to New York Flight Service. When your shift comes on you'll be answering calls from pilots. They'll be giving you their flight plans and you'll need to give them weather information. Do your best to interpret the data from the weather products on your console and help the pilot make an informed decision." At this point, the learner can take a "call" from a pilot requesting a briefing such as, "Tail number 666 Whiskey X-Ray, departing Albany at 3:30 local time direct to Islip. VFR at 3500 feet, and will be approximately 1 hour and 15 minutes en route," [Fig. 2]. The audio is complemented by an annotated transcription that maps the pilot's request onto the parameters needed by the student, *e.g.* the time of departure and the proposed route. Once the learner takes a call he or she sets out to construct a briefing similar to those provided by FAA specialists. The elements of a standard weather briefing include adverse conditions that might suggest alteration or cancellation of a proposed flight (such as a thunderstorm, icing, or severe turbulence); a synopsis as to the cause of the weather (*e.g.*, fronts or pressure systems); current conditions; en route forecast; and destination forecast.

The students would then proceed to gather data relevant to the pilot's request from an array of weather products such as surface weather reports, terminal forecasts, weather depiction charts, radar summary charts, and significant weather advisories. Associated with each of these maps and reports will be explanations of how each should be interpreted and supplementary advice, such as potential ambiguities arising from a particular source of information [Fig. 3]. In the example case, the weather depiction chart might indicate that a cold front is approaching the destination; the student would be given hints to point out the possibility of a frontal thunderstorm. Since the issue at hand is whether this represents a threat to the pilot's proposed flight, the main concern is whether a thunderstorm will develop, and if so, whether it will be a factor along the proposed route. In the student's investigation, he or she has access to a number of predictive sources that might suggest that a storm is likely to develop. Suppose, though, that no thunderstorm activity is being reported by any surface observation stations or by pilots en-route. How should the student reconcile the forecasts with the observations?

The program might suggest at this point that the student consult satellite imagery, for instance, which would show evidence of building towering cumulus clouds (the progenitors of cumulonimbus or thunderstorms) along and ahead of the front [Fig. 4]; returned echoes on the radar imagery could indicate regions where precipitation is forming within young thunderstorms. Having now identified an adverse condition and its cause, the student would proceed to apply his or her new understanding of frontal systems into the emerging briefing.

Once the learner delivers the briefing and makes a recommendation, the program provides feedback on the student's performance, including the (simulated) results of the pilot following the student's recommendation, a briefing (for the same flight) prepared by an actual briefer, an explanation of how this specialist constructed his or her briefing, and the (real) weather conditions that obtained during the (simulated) flight.

Building Understanding from Analysis and Synthesis Tasks

Wx-Brief is intended in part to illustrate an instance of a model called Data Analysis for Understanding Global Systems (DAUGS) that integrates content-domain knowledge, software simulation, data visualization software, and real time Internet data.[2] The model calls for the learner to prepare a set of predictions (*e.g.*, a briefing or recommendation) for agents in various situations who are dependent on the accuracy of the learner's predictions. The model is intended to be applicable, at a minimum, to Earth Science instruction at the middle and high school level, though it is likely to have broader utility.

DAUGS model as a framework for Earth Science Inquiry

"Understanding Global Systems" reflects our emphasis on a systems approach to Earth Science, which we have selected as our target domain for two reasons. First, Earth Science is a reasonable anchor from which applications in other domains could be created, since the scientific methods of inquiry and theory-building emphasized in the proposed model are important and broadly-applicable cognitive strategies. Second, Earth Science is an inherently accessible and understandable area of science [Kastens 1995]. "Data Analysis" suggests our focus on engaging students in the inquiry process, which enjoys broad support [Dewey 1938; Gagne 1977], and has been noted in particular in the realm of science instruction [Brown, Collins, & Harris 1978; Simon 1977; Tweney, Doherty, & Mynatt 1981].

Related instructional frameworks

The DAUGS model has roots in two general frameworks: Goal-Based Scenarios (GBS) and Interpretation Construction (ICon). *Goal-Based Scenarios* [Schank, Fano, Bell, & Jona 1994] offers a general structure for learning-by-doing, simulation-based educational software. The GBS framework calls for placing the student in a role in which the target skills and knowledge will be encountered during the course of pursuing some goal relevant to the student's role. Interpretation Construction [Black & McClintock 1996] is a model that calls for students to learn about a topic by making basic observations (raw data collection), then constructing interpretations of those observations while accessing multiple background materials and being coached by a teacher expert in the topic area. Empirical studies have provided preliminary support for both the GBS [Bell, Bareiss, & Beckwith 1994] and ICon [Black, McClintock & Hill 1994] frameworks.

---

[2] The Wx-Brief application is designed to accommodate the use of real-time data but this element of the software has not been implemented.

Figure 4: Secondary materials foster comprehension of thunderstorm formation factors.

Using the model to appropriately constrain and sequence content

The mere availability of technological resources that might support a Goal-Based pedagogy does not, in and of itself, yield any clear instructional design principles, and it is at the level of instructional design that teachers and researchers have had some difficulty translating emerging potentiality into effective classroom practice. We offer that the dominant design problem for educational scenarios that are goal-based and premised on interpretation construction is the proper constraint of the learning environment.

[Swan & Black 1993], [Harel & Papert 1991], and [Kafai 1995] have all demonstrated, in the context of teaching programming fundamentals and problem solving techniques through Logo, that a carefully constrained learning environment results in far more acquisition than a largely unconstrained, open-ended exploration. Similarly, [Riesbeck 1996] has argued that goal-based scenarios that provide powerful tools but little other formal instruction or modeling are akin to the teaching of carpentry by providing a learner lumber, saw, hammer, nails but no carpenter to whom to apprentice. The DAUGS model casts learning in part as an act of pattern recognition. The experienced scholar or professional is able to identify patterns in complex data, discriminating between relevant feature and "noise". Recognizing relevancy and filtering out noise requires experience with a broad range of cases that attune one to essential characteristics [Gibson 1977; Greeno & Moore 1993; Greeno 1989; Lave 1988; Suchman 1987].

For a student of Earth's environmental systems, relevant patterns may be difficult to recognize because instances of a category may be idiosyncratic and, in ways not germane to interpretation, diverse. Most cold fronts, for example, are accompanied by cooler air, but often during summer months they are instead accompanied by warmer air; relative to their effects on wind and dew point, for instance, this diversity is irrelevant and both cases are properly recognized as cold fronts. This type of complexity in a knowledge domain has been discussed as its "ill-structuredness" [Spiro et al. 1991]. In a convincing analysis of expertise, Spiro et. al. have described experts' appreciation of ill-structuredness as a result of having "criss-crossed" the landscape of a knowledge domain to such an extent that family resemblance among cases is recognized amid all the idiosyncrasy. The DAUGS model is designed to enable learners to work with data in a way that attunes them to the knowledge domain's complex structure.

Conclusion

Our discussion of Wx-Brief serves both to present an engaging and instructionally meaningful learning environment, and to demonstrate the application of an instructional model. The interaction between the student (as weather briefer) and the (computer-controlled) pilot situates the task of understanding weather within a compelling task context, and illustrates not only a set of principles but their utility as well. The underlying model, Data Analysis for Understanding Global Systems, prescribes a task environment in which the learner engages in formulating a recommendation based on inferences drawn from available data.

BEST COPY AVAILABLE

One aspect of the model absent in the demonstration application is the use of real-time information. Simulated environments such as Wx-Brief use simplified data to provide clear opportunities for concept formation, engaging students in the process of learning by doing. In contrast, access to real data sources provides authentic opportunities for outcomes prediction in evolving situations, offering a field for the application of concepts attained through goal-based simulations and other concept-formation activity. Although each technology has particular strengths, little work has been done to systematize how they may be applied in concert to the best instructional advantage. Two aims of the DAUGS model, and the applications it shall inspire, are to exemplify the appropriate use of simulated versus real contexts for scientific study, and to introduce teachers to classroom simulations combined with real data access as a powerful strategy for science learning.

Teletesting: Design and Implementation Issues

Bryan P. Bergeron, MD and Michael T. Bailin, MD
Bergeron@hstbme.mit.edu Bailin@etherdome.mgh.harvard.edu
Harvard Medical School, MGH Anesthesia & Critical Care
Fruit Street, Boston MA 02114

Abstract: Evaluation is integral to most educational designs. As such, teletesting is evolving into a key component of computer-based distance learning systems. Teletesting promises a number of advantages over local or fixed-site testing, including cost and time savings for participants, as well as increased flexibility. However, there are a number of issues related to teletesting systems that are often of less importance in systems designed for only content delivery. These issues, which may be related to the increased significance of test results, include: privacy; environmental consistency; legal concerns; security; hardware platforms; cheating; network infrastructure and bandwidth; image transfer and display capacity; test generation location and method; distribution media; and testing design.

INTRODUCTION

Testing is an integral component of learning, whether this learning is accomplished through conventional, local computer-based, or distance learning environments. Testing can be an obviously separate component of a computer-based learning experience, or an integrated component of the pedagogical design, such as when a gaming approach is used [Bergeron and Fallon 1990]. Computer-based testing of all forms is gaining popularity in a number of areas. Not only are SAT, GRE, and private pilot examinations now offered via computer, but computer-based testing becoming an important option for many professionals seeking competence assessment [Friedman 1986] as well as licensure and recertification [Clyman 1990; Sumner and Truszzynski 1995].

Unlike self-examinations and other testing options used primarily as an aid to self-study, many computer-based tests now hold considerable weight. That is, there are increasingly instances when the consequences of testing, and therefore the pressure to score well, are great. In medicine, for example, a number of medical boards are actively pursuing teletesting alternatives to the current practice of on-site oral and written exams for recertification. The pressure to pass these examination once every 3 to 5 years is enormous. For example, some medical board exams are currently offered only once per year; failure to pass these oral and written examinations precludes practicing medicine until the next exam. Currently, heavily monitored recertification examinations are subject to challenges by those failing to pass examinations. Obviously, any aberration from a perfect, standardized testing environment that can be identified by someone failing to pass an examination will be used in their defense.

In part because of the weight placed on the associated results, teletesting system requirements can be very different from those used strictly for delivering instructional materials over a distance. Some of the more significant issues in teletesting include: privacy; environmental consistency; legal concerns; security; hardware platforms; cheating; network infrastructure and bandwidth; image transfer and display capacity; test generation location and method; distribution media; and testing design. As outlined below, many of these issues can be attributed to the bi-directional data flow requirements associated with program instrumentation [Bergeron 1990], the potential variability in testing environments, and the need to guarantee the security and accuracy of the testing content, the testing process, and test results.

Teletesting Issues

Many of the issues relevant to teletesting pertain equally to any testing situation: the need for privacy, a constant, repeatable testing environment, security for testing materials and to insure valid test results (i.e., no cheating), and adequate help when it's needed. Other issues relate directly to computer-based testing, such as hardware adequacy and consistency, the suitability of the network infrastructure (if applicable), test content generation and validation, the distribution media, and the validity of the overall computer-based testing approach. The main issues and possible solutions are described in more detail below:

Environmental Consistency

For test results to be valid, the testing environment, which encompasses not only what the user experiences on the computer, but also the ambient noise, glare, potential distractions, and creature comforts. Everything from the relative humidity, temperature, time of day, chair comfort, video display height, and provision for left- or right-handedness defines the testing environment. If users are to be scored relative to one another (as is normally the case), the teletesting environments should be as identical as possible in these and other parameters, in fitting with the significance of the test results. Possible solutions include: establishing and enforcing standard hardware configurations (e.g., 17" monitor, 200 MHz Pentium processor, 56K Modem), including calibrated monitors and sound equipment.

Privacy

Related to environmental consistency, users normally expect a degree of privacy or at least freedom from distractions. Privacy may mean very little to someone in an engineering firm involved in a self-study program on their free time, but may be of paramount importance to a physician taking a six hour recertification examination remotely. In high-visibility teletesting situations, such as a when results impact directly on licensure, privacy may be insured by providing dedicated testing areas. However, remote testing centers are generally an expensive option, especially if no other use for the centers is planned. Reasonable solutions include: use of partitioned computer testing areas (e.g., a school's computer learning resource center), restricting the use of voice recognition interfaces, and appropriate visual barriers between computer stations.

Security

Unlike a proctored computer-based examination, where one or more trained examiners are available to observe any unusual behavior on the part of the test takers, teletesting must rely upon trust and, increasingly, technology. For example, just as floppy discs and even CD-ROMs can be copied, content and questions delivered the WWW or other network can be easily captured and redistributed. Unforeseen circumstances, such as unexplainable, sudden power outages or unexplainable computer failures can also be provided for somewhat by relying on network-based teletesting. For example, someone unhappy with their current score could potentially unplug their computer, make several duplicates of the distribution floppy to access "practice" examinations, or somehow decipher how the test score and tracking data are recorded and create a falsely inflated record.

When test content is distributed via a network, however, attempts at breaking security checks can be limited. It is possible, for example, upon computer failure to either refuse a retest at a distant site or to simply regenerate another exam, completely different from the first. This is possible with remote storage and generation of exam content. Such an approach, however, makes certain assumptions about the stability and performance of the hardware platform and network bandwidth. Alternatively, a remotely-activated digital camera, directed at the user, can be used to randomly record frames of the user interacting with the testing system. Such remote monitoring may be sufficient to inhibit the use of unsanctioned support materials or hardware tampering.

Validation

Related somewhat to security and environmental consistency, validation of the remotely administered test must somehow encompass how well the test measures what is intended to be measured. Compared to traditional computer-based testing, where many of the environmental and hardware factors can be held constant, determining the validity of a teletesting scenario can be challenging. For example, in an image-intensive test requiring on-screen display of medical radiographic or photomicrograph images, variations in monitor size, dot pitch, phosphor composition, refresh rate, or even contrast setting can mask or enhance significant image features. Similarly, a trackball on one system might give the user an unfair advantage or disadvantage compared to someone using a system with a mouse or light-pen. Ideally, the test scores should be minimally influenced by the user's proficiency with specific hardware. To this end, evaluation techniques, such as control groups, management objectives, regression analysis, case analysis, and cost-based analysis can be used in assessing the validity of a specific teletesting application [Moad 1995]. Other solutions include adhering to a standard user environment, as discussed above, and heavy reliance upon program instrumentation techniques.

Legality

Given the significance of some teletesting results, it can be expected that people who fail to achieve passing scores will challenge the system. For example, in medical recertification examinations given orally or in controlled written test situations, physicians who fail these tests routinely challenge the medical board on the validity of their assessment tools. Given that teletesting is in large part unproved, legal challenges can be expected to increase before teletesting becomes an accepted reality. Tentative solutions include: thorough program instrumentation so that specific cases can be regenerated for expert analysis if need be; comparative studies relating performance on locally administered versus remotely administered examinations; and a through validation of the overall teletesting strategy.

Hardware

In the context of this discussion, teletesting is totally dependent upon a computer system capable of providing images, video, text, or other content as appropriate for testing purposes, as well as a means of capturing and processing user interactions with the testing software. The hardware platform and associated supporting infrastructure define the upper limits of fidelity and overall capability of the testing system. For example, multimedia-rich applications may minimally require high-fidelity audio playback hardware and associated speakers, video playback hardware capable of real-time 3D rendering and video decompression, and a high-throughput CD-ROM drive. A hybrid or WWW-based system may additionally require a high-speed modem or the appropriate Ethernet hardware. As described above, the solution to the hardware dilemma seems to be linked to establishing a standard testing platform.

Network Infrastructure

Despite the exponential growth in WWW capabilities and popularity, the network infrastructure has quickly become the limiting factor in remote testing and education delivery. Although there are currently significant security and bandwidth limitations, the WWW is quickly evolving into THE standard means of delivering educational materials. Even when teletesting is based on programs distributed by CD-ROM or floppy, network connectivity can be used as the basis for communicating program instrumentation data back to a central, secure repository. This method of data collection can be expected to rapidly replace the current practice of requiring users to mail floppies to a facility where the tracking files can be examined and scored. Issues surrounding network infrastructure should be resolved with the increased bandwidth and connectivity promised by constantly evolving network architectures.

Distribution Media

The hardware platform and network infrastructure, together with marketing, demographic, and economic issues, define the optimum distribution media for teletesting applications. For example, high-speed Internet connectivity, although commonplace in academic institutions, has yet to become the norm in many isolated communities that could benefit the most from telelearning and teletesting. Similarly, although virtually all PC's sold today come with CD-ROM drives as standard equipment, new, high-end PC's tend to be rare in remote, rural areas. Distribution on inexpensive floppies limits the teletesting environment to predominantly text, with few graphic embellishments. Obviously, the distribution media of choice can be expected to evolve rapidly to hybrid CD-ROMs and the Internet. The issue of distribution media may well be solved on its own as bandwidth increases, and as distribution relies on multiple avenues of delivery.

Content Generation

Perhaps the most resource intensive component of any teletesting system (or local testing system, for that matter) is that of content generation. The difficulty associated with creating a library of images and associated questions, together with a valid answer pool, is related to the many of the issues described above. For example, if security is lax, a larger library of content is required, so that multiple tests can be generated with minimal duplication. Similarly, if great cost is incurred in creating content, such as in rather lengthily medical recertification examinations, then some automated means of content generation may be optimal. However, automatic generation of content, especially if this generation occurs at the user's site, presents several validation challenges. Exhaustive program instrumentation can help identify any aberrations in such content, but this has its own security and hardware platform issues. For the short-term, the best solutions seem to revolve around remote content generation, and extensive libraries of images, sounds, video, and text, e.g., institution- or corporation-wide multimedia libraries.

Summary

Teletesting is quickly becoming an integral component of distance learning. Proper attention to the issues discussed above, especially those pertaining to potential abuses by unscrupulous users and provision for consistent hardware and network infrastructure will help insure the viability of teletesting. The ultimate success of teletesting rests on the ability of those involved in the larger computer-based testing field to perfect and validate the medium.

Abstract: With ever present financial and human resource constraints, universities must find innovative ways to preserve the standard of education students receive, given the limited help resources presently affordable. One way to achieve this is to utilize technology in providing individualized help. This paper focuses on the design of the Co-operative Peer Response ("CPR for students") project - a system that seeks to address these issues. The rationale and context of the project and a preliminary evaluation of the system are also provided.

1. Introduction

This paper presents the Co-operative Peer Response ("CPR for students") project and provides the rationale and context for the project. The problem that is being addressed is the effective distribution and utilization of help resources in a university course setting. As University budgets are under constant pressure and class sizes continue to grow, new ways must be found to preserve the quality of education received by students. One way to do this is to utilize technology in providing individualized help.

Students generally only seek help just prior to major academic deadlines. This surge in help requests is compounded by the fact that there is a wide disparity in the nature of the help and the manner in which help is solicited. Some students are bold enough to request help during lectures or tutorial sessions. Others will only consult the instructor in a private setting. A large majority of students will rarely ever ask instructors for assistance, preferring to ask classmates and peers. Student study habits also hinder the effectiveness of traditional help resources. Since help is generally available during traditional working hours and many students work nocturnally, the available help is not utilized effectively. Due to financial cutbacks, lecturers and laboratory assistants may become overwhelmed with help requests, many of which are variations of the same questions that could easily be answered by the peers of the help requester.

The main objectives of the Co-operative Peer Response system are to capitalize on a generally underutilized, but nevertheless important resource: the students themselves. In doing so, this modified Web-based Frequently Asked Question (FAQ) system will also meet the following sub-objectives: to provide help specific to a particular class context; to identify and use the expertise of class "gurus" (local experts); to accommodate both public and anonymous help givers/seekers; to get a better understanding of how help resources are utilized, and to get a more accurate assessment of the problems students find most difficult in the course.

2. Present Help Resources

Existing help facilities in university courses fall into three broad categories: printed material, human to human interaction, and electronic support [Jenssen 93]. Printed help material is produced in one central location and is uniformly presented to the students. However this may be a costly or inefficient method of dissemination.

Human help resources such as instructors, laboratory assistants and tutorial leaders are expensive and heavily loaded. There is also a generally unacknowledged, but important, help resource in most courses: peer experts, who invariably help many of their fellow students with assignments [Bannon 86]. Human help makes it easier to identify exceptional students, in turn leading to a more accurate method for evaluating students and assessing their problem areas.

Help Desks (such as telephone help desks) are not generally deployed in particular courses, but rather on an institution-wide scale, especially for technical questions. This method of help support, though serving many users, is not a mass help medium like an FAQ, as the type of user interaction is personal and a great deal of the time is spent repeatedly answering the same questions and establishing the context of the problem. Help desks are generally used as a last resort when no local expert is available to answer the question.

Enrollment increases in university classes have made human help and print resources inadequate or infeasible. Electronic tools provide a relatively cheap means to augment help resources. These tools includes newsgroups, electronic mail, mailing list servers, the World Wide Web, groupware, computer conferencing software, and electronic help desk support.

Electronic mail (email) and mailing lists (listservs) are popular at universities. However, since everyone in the group can contribute their ideas, in a large listserv, sorting and organizing the messages is an arduous task placed on the group member. A large load is also placed on hardware resources as there are usually many copies of the same email documents stored.

Newsgroups, like listservs, include the viewpoints of many users leading to a better overall discussion, without the same intrusion and excessive usage of hardware resources. Newsgroups give the possibility of incorporating many types of Internet resources (ftp, gopher and Web sites). The ability to thread and organize the information that subscribers (newsgroup users) submit and view is yet another advantage. Organizational responsibilities for newsgroups fall on the moderator rather than the subscriber. Important postings can be archived for future use. The immediate nature of a newsgroup posting means that instantaneous responses to queries will occur. The main problem that most newsgroups face is their lack of use, due primarily to the more glamorous communication alternatives (e.g. the Web, groupware, and computer conferencing) available.

The Web can disseminate help material of a textual, visual and aural nature, reducing the cost of printing. Updates are easily done. The Web, through the use of conferencing applications like WWWBoard [WWWBoard 96] and NetForum [NetForum 96], can offer the same services that newsgroups provide.

In most departments, the primary use of the Web as a help tool is with lists of Frequently Asked Questions (FAQs). FAQs are useful only if sufficiently populated with up-to-date questions and answers, and the help requester is able to properly formulate queries and find answers that exist somewhere in the list. FAQs are ineffective if the question has never been asked before. The maintenance and organization of FAQs, as well as answering user queries is usually done by an expert (the moderator). Unlike a newsgroup, little use is made of the latent pool of knowledge that the users' peers possess. Some FAQs allow peers to answer the queries of other users, but these are the exception rather than the norm.

Lotus Notes [Notes 96], and Microsoft NetMeeting [NetMeeting 96] are popular commercial groupware and/or conferencing packages, but they place hardware and financial constraints on the institutions that use them. Some applications such as Motet [Motet 96] have database support which aids in the organization and customization of material presented. These products are not usually tailored to the specific needs of university courses.

WebCT [WebCT 97] makes it easier to create web pages, monitor user accesses and evaluate students. It supports email, newsgroups and chat facilities. However it has no real database support and this limits the additional benefits that should be derived from an application of this nature. For example user modeling, customization, information filtering and a good search engine are difficult to implement, since a detailed knowledge of the internal representation of the data stored is necessary.

All of these methods of providing help have their own strengths and weaknesses. Some can cater to several types and numbers of users, while others are limited in their potential use. The more personal forms of communication such as email and telephone help desks can be used by the "anonymous" help seeker but in this method the group generally does not benefit from the interaction.

3. The Design of "CPR for Students"

The CPR Project is an attempt to capitalize on the strengths of the current support tools, while minimizing their weaknesses. The Co-operative Peer Response System provides the following: a newsgroup-like facility where students can post questions or comments; an interface to support rapid responses from peers, tutors, or instructors; an accounting system to recognize students who provide and use peer help; an FAQ facility; tools to aid the moderator in constructing and organizing the FAQ, and a database of potential peer helpers. The system is customizable to a particular course, providing peer help and FAQ facilities via the Web. [Fig. 1] gives a conceptual representation of the CPR architecture.

At the core of the CPR system is the extensive use of a database [Fig. 1]. The database tracks interactions between the user and the system, is used to create and maintain web pages, and keeps a profile of each user. To keep the posted material relevant to the particular class, access to the system is restricted to registered users. CPR uses only standard HTML tags on all of the pages, and is therefore accessible to both textual and graphical browsers. The system has two sources of help information available: a rapid response area, called the Recent Questions and Answers page, and an archived section called the Moderated FAQ.

Figure 1: The CPR system architecture

3.1 Recent Questions and Answers Page

The presentation and function of the Recent Questions and Answers page is similar to a newsgroup, with the content provided by the users themselves. Links to the latest questions and their associated replies are stored on this one HTML page, which is used to organize and index the information found in each separate question file. The most recent questions are placed at the top of the page, and the most recent replies to a particular question are placed at the top of that particular list of replies. This threaded scheme is used in both the Recent Questions and Answers index page [Fig. 2] and the individual HTML page for each particular question and its replies.

Each entry in the Recent Questions and Answers page consists of a class-specific category or topic; an author (who may be anonymous); subject and keywords (both optional); the posting time; and the text of the question, comment or reply.

If a student posts a question, a peer can post a reply immediately. Thus help can be available to the user on demand. The class experts can be extremely useful in this medium, increasing the possibility of many good solutions being proposed for the same problem. The moderator is also equipped with tools to quickly remove/add entries to the Recent Questions and Answers page. This way erroneous postings can be quickly corrected.

3.2 User Input Help Forms

To help formulate the user contributions and make the postings uniform and easy to understand and navigate, forms are provided. The two types of forms used are the Submit Question and the Submit Reply. The question form contains six fields. The name of the user need not be entered since it is obtained from the database. An option exists for posting anonymously, or publicly (such that the user name, web page and email addresses appear). Users have the option of posting a question or a comment. (The default is a question.) A course specific category table, a list of class specific topics and subtopics chosen and entered by the moderator and instructor is also provided. There is no default category and the user MUST select one from the list in order to successfully submit the entry to the Recent Questions and Answers page. Subject and keyword fields (both optional) are provided for indexing and threading purposes. The text field, where the actual user entry is placed, can be enhanced with HTML tags. (The default is plain text.)

A reply button immediately follows each entry on the HTML page displaying a question and its replies. The reply button brings up a form that has the following fields: user name, text field, public/anonymous posting, and question/comment options, also found on the Submit Question form. Also displayed is the item (question or reply) that this reply is addressing. Optional subject and keywords fields initially contain the subject/keyword from the parent message by default. The user has the option of changing these fields.

Figure 2: Recent Questions and Answers Web page

In using both of these Web forms there is an intermediate Preview step that all entries must go through before the item is added to any page. This is important because it gives users the chance to edit their entries as many times as they like before posting. Preview also makes it possible to abort an entry prior to submission. The fact that the entry may contain HTML makes the need for a Preview option even more vital.

3.3 Moderated FAQ and FAQman

The Recent Questions and Answers page periodically needs to be pruned to remove outdated entries. Some of these entries might be discarded, but others should be entered into an archive (the Moderated FAQ) for future use. The design of the Moderated FAQ pages is similar to a traditional FAQ, with a list of class topic categories, cross postings of messages in relevant categories, and a table of contents to organize the postings.

A problem with traditional FAQs is maintaining the consistency of messages that have been posted under several topics, or easily adding to or removing entries from one or more FAQ subtopics. CPR handles this by manipulating the structure of the FAQ pages through modification of the underlying database. Each time the FAQ web pages are reconstructed, updates are automatically made by using the information in the database. This method also makes it easier to maintain consistency when the actual text of the FAQ entry has been modified. There is no longer a need to cut and paste from several files. Only the moderated FAQ entry itself needs to be updated as the changes are reflected in all of the relevant class category pages.

The job of the moderator is made easier because the main task is to organize and maintain the archive by selecting the best peer questions and answers, rather than to dream up questions and provide answers to all of the questions. The majority of the questions will be answered by the user's peers and only the really difficult ones need the moderator. The role of the moderated FAQ is to serve as a repository of reference material available to the class. The information can be expected to be accurate since it was edited by a knowledgeable individual before inclusion, usually after being proposed by classmates.

FAQman, a stand-alone application developed under X-Windows, allows the moderator to allocate credit to students who asked good questions or made useful replies. [Fig. 3] shows a screen shot of FAQman in action. All of the items found on the Recent Questions and Answers page [Fig. 2] are displayed in the frame labeled "xfaqman" [Fig. 3]. From here the moderator can assign credit to the users who posted these messages as well as remove the postings from the Recent Questions and Answer page. He can add, delete or modify entries in the Moderated FAQ pages by using the "Item Editor" frame (invoked from "xfaqman"). These Moderated FAQ

BEST COPY AVAILABLE

items may either be created from Recent Question and Answer messages or from scratch. FAQman allows an item to be posted over several categories. Only one copy of the entry is stored in the database. The Moderated FAQ consists of a set of web pages with "include" statements and any modifications made to an item are automatically reflected in all of the pages that reference it. The text of the highlighted entry appears at the bottom of each of these frames. In "xfaqman" the entry can only be viewed, while in "Item Editor" the Moderated FAQ item is modified here.

4. Other Features of CPR

CPR has an anonymous area where user concerns and suggestions can be freely expressed. The Anonymous Flames and Suggestions (AF&S) page uses a script that creates a text file, with no means of identifying the sender, that can be used as part of an anonymous evaluation of CPR. The system also provides class email and web page address listing of all the class participants. Password resending scripts are provided to help users choose (and remember) the passwords they desire.

Why would students want to use the system to solve peer problems? One answer is that they too may also need help from the system one day, and if they provided assistance in the past, the favour may be reciprocated. Another reason is that a portion of their course work can be allotted to participation in the use of the system. In this manner, using CPR for students could be a part of the class participation grade.

5. A Case Study Using CPR

At the time of writing, CPR for students had been deployed in two third-year computer science courses each with about 90 students. One of these was a programming intensive operating systems course, while the other was an information systems and Software Engineering course. In the first semester of operation, some interesting preliminary observations and results were noted. Results were obtained from actual observation of the system in use, data provided by the users, and looking at Web server statistics.

In both courses, the system was used frequently with an average of about 250 hits per week by students. The number of hits in the Operating Systems course was slightly higher than in the software engineering class. The average number of postings per week was 30-40 for both courses. The operating systems instructor was a fervent user of electronic help resources, heavily utilizing email, listservs and the Web in previous courses to communicate with his students. This heavy use was also evident in his postings to the Recent Questions and Answers page, as he was one of the most frequent contributors. It was also noted that in this course, many of the harder questions were answered by the instructor or moderator, sometimes anonymously. Apart from this, the level of class participation was relatively widespread across many members in the class, and multiple postings by the same user were not uncommon.

Few of the postings were made anonymously, with students asking any questions they considered relevant to the courses. In both courses, the types of questions posted were typically quite brief and not too

BEST COPY AVAILABLE

technical and there were usually several peer responses per entry. Student evaluation of CPR in both courses was most favourable.

6. Conclusions

This preliminary evaluation of CPR has produced the following conclusions. The system, as designed, works reliably. Usage statistics showed a good level of usage of CPR and signs of active acceptance by instructors, moderators and students. The CPR system provides statistics about patterns of student use that instructors can use to determine where further explanation in class is needed. Based on the appraisals of instructors and the comments of moderators and students there is apparent satisfaction with the system. Some of the suggestions given have already been implemented in the newest version of CPR [CPR Demo 97].

Many of the features of WebCT can easily be or have already been incorporated into CPR. The database support of CPR can be extended to incorporate user modeling and information filtering. Work has already begun on a search engine, and the individualization of information filtering is one of the next goals.

To determine what future changes must be made, a more detailed evaluation of the benefits and potential problems with the system must be carried out. Two aspects of the system will need to be addressed in the immediate future. The primitive nature of the database (Mini SQL) presently used in the CPR system poses serious limitations. This is easily solvable by using more reliable and powerful database tools. The current version of FAQman is limited to an X-Windows platform. This will be made more portable once the Web based version is implemented in Summer 1997.

At the University of Saskatchewan, CPR has been deployed in more computer science courses for Spring 1997. One of these is a distance education course. The final goal is full scale use by Fall 1997. Instructors are optimistic that the increased emphasis on peer collaboration can lead to the strengthening of peer bonding and the formation of informal study and help networks.

Long term plans include making use of the CPR database to create individual student models. This will facilitate better deployment of departmental human and printed help resources to meet individual needs. It will also facilitate identification of student misconceptions so that individualized remedial actions can be taken, and identification of student strengths to determine potential peer help resources from within the class.

Abstract: Since 1995, Broadcom, a telecommunications research company, has been providing Internet access to three schools in Ireland as part of a project named "Classroom of the Future". This paper describes the technical and educational issues addressed by the project and makes recommendations on the use of the Internet in the classroom.

1. Introduction

This paper describes Broadcom's experiences in the application of high-speed Internet access to schools in Ireland. The experiences detailed were obtained as part of an on-going three-year research project investigating the uses of telecommunications technology in education. The project was divided into three phases.

In the first phase, Internet access via ISDN (Integrated Services Digital Network) was provided to three schools in the Dublin area in September 1995. The project involved the installation of the technology, providing training and support to the teachers, monitoring and encouraging the use of the facilities, and investigating future applications for telecommunications in education.

Based on the results of the first phase, the second phase of the project was launched in May 1996. This phase involved the development of a Web Site, a guidebook and an informational poster. These materials were designed to encourage and facilitate Irish teachers in using the Internet in their schools. The guidebook and poster were distributed free of charge to schools throughout Ireland.

The third phase of the project is to study longer term issues associated with the introduction of telecommunications into the classroom. It is intended that it examine some of the educational questions in more detail and the application of more innovative technology will be investigated.

2. Background

Broadcom is an independent telecommunications research company based in Dublin, Ireland. The company was established in 1987, as a joint venture between Telecom Eireann, Ericsson and Trinity College, Dublin. Broadcom specialises in research and consultancy in the areas of network management and advanced telecommunications services.

In 1995, it was suggested by Telecom Eireann that Broadcom undertake research on applying telecommunications to education. As a result, the "Classroom of the Future" project was initiated.

At the time of the project's launch, the uptake of Internet technology in Irish schools was quite low. However, the number of Irish schools that are on-line has increased rapidly over the past year. At the moment, we estimate that, of the 780 secondary schools and 3,200 primary schools in the Republic of Ireland, roughly 500 are on-line and 50 have developed home pages. It is noticeable that the on-line schools tend to be situated in more affluent areas or have particular demographics. For example, schools on the Aran Islands, an Irish speaking region, have specially funded computer and ISDN facilities. Most of the major Internet Service Providers offer free connectivity to schools. Overall, Irish teachers are of the opinion that computer education in schools is inadequately funded.

3. Phase 1 "Bringing Down The Walls Of The Classroom"

3.1 Approach

The aim in the first phase of the project was to investigate how telecommunications and computer technology could be used in the classroom.

Since the Internet is the most widely available telecommunications information resource, it seemed logical that our starting point be to provide Internet access to a number of schools and to study its uptake in the classroom. In addition, the decision was taken to provide high-speed access using ISDN. ISDN provides access speeds of up to 128 kb/s and can support a class sharing simultaneous Internet access via the school LAN (Local Area Network).

Three schools were identified as having appropriate facilities and a motivated teaching staff. These schools were Pobalscoil Neasain (secondary, ages 12-18), St. Andrew's College (secondary) and Good Shepherd National School (primary, ages 5-11). A steering group, or Project Advisory Group (PAG), for the project was then formed with representatives from Broadcom, from the schools involved and from the Blackrock Education Centre.

Internet access was provided to the three schools in September 1995 [Jeacle 1997]. Broadcom installed a PC in each school to act as an Internet server for the school LAN, see [Fig. 1]. These servers were configured with the Linux operating system and had an ISDN Terminal Adapter card installed. The Terminal Adapter cards are connected to ISDN lines supplied by Telecom Eireann and wholly subsidised by Broadcom. Thus, via the server and the ISDN network, the schools can access the Broadcom corporate LAN. This allows them to access the Internet via Broadcom's permanent leased-line connection supplied by Eunet, Ireland. The overall system provides the schools with high-speed access to the World Wide Web (WWW), Telnet, FTP and E-mail.

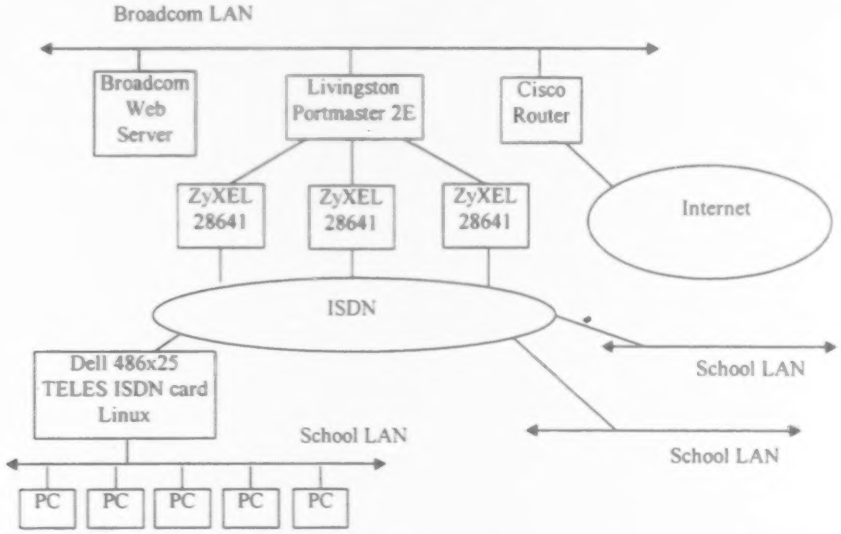

Figure 1: Schematic diagram showing the network configuration used to connect the schools to the Internet via the Broadcom corporate network.

The network configuration described was selected for a number of reasons. First, the Linux servers were cheap to set up and maintain, Linux being a free UNIX implementation. Second, ISDN is well suited to school Internet usage patterns since schools tend to access the Internet sporadically - intensive usage occurs during an Internet-related class, while there is almost zero usage during the summer months. Unlike its leased-line connection to Eunet, Broadcom only pays for the ISDN connections to the schools while they are in use. Third, ISDN allows high-bandwidth access to the Internet, so entire classes can use the facilities simultaneously. Finally, with ISDN the schools are not limited to just connecting to

BEST COPY AVAILABLE

Broadcom - ISDN video-conferencing is possible with other schools, businesses and government organisations around the globe. In fact, the Good Shepherd National School has conducted a live video-conference with European Union (EU) ministers.

3.2 Findings

Our findings during phase one are described below. The findings are grouped into three categories according to the use made of the facilities by the schools. The three main uses were found to be: using the Web as a giant reference library, using a home site to promote the school and using E-mail to communicate with other schools.

3.2.1 A Giant Reference Library

Initially the schools used the Internet as a giant, up-to-the-minute reference library. Topics such as the weather proved to be a good starting point. The material was clearly relevant to the subject at hand, in this case geography, and the Web provided easy-access to well-presented, up-to-date information. Similarly, access to foreign language material, such as French newspapers, was deemed very useful since text books are frequently a little turgid and dated. Science is another area which is well represented on the Web. Perhaps not surprisingly, there is little material available on the Irish language. It is hoped, however, that, as it has already done for other interest groups, the Net will draw together geographically disparate groups interested in the Irish language.

The teachers found this reference library approach to the Web to be of use both for themselves and for their students. The teachers found that they could easily and quickly find new and relevant material for incorporation in their teaching activities. Also, they found that allowing the students to seek information themselves was a very positive exercise. First, the students, almost unwittingly, became efficient and confident in using the computer technology. In fact, it was noted that Web browsing is an effective introduction to the use of computers in general. Second, the technology enabled user-driven learning strategies. The students were set a goal and were required to do their own research, evaluating and assessing the information they found along the way. In some cases, it proved that this user-driven learning approach was almost too powerful for the teachers.

In the conventional classroom situation, the teacher "stands and delivers" the lesson. The teacher controls the class and directs their learning. In this context, the teacher is familiar with all the educational material available to the students and can, to a high degree of accuracy, predict what answer they will come up with. In the Internet-enabled classroom, however, the teacher is not familiar with all the educational material available. The teacher does not know what answer they will uncover and, due to the very nature of hypermedia, does not know what path they will use to find a solution. The scenario has shifted from one in which the teacher is the high priest of knowledge to one in which the teacher is the gatekeeper of knowledge.

In our experience, some teachers are unwilling to accommodate this shift in the education paradigm. Some refuse to "let the children loose". They are uncomfortable and feel that the class is out of control. The only way to approach this problem is to equip teachers with the strategies and tools appropriate for this new form of teaching. The teachers themselves must be educated in integrating the new technology into their classroom methods. The problem is not just one of training teachers to use the technology, but is also one of training teachers to use the technology to educate effectively.

3.2.2 A Means For The World To Look In On Your School

Later, as the teachers and students grew in familiarity and confidence with the new technology, some of the schools developed their own home pages. It quickly became clear that school home pages fall into one of two basic categories.

The first category consists of home pages produced by a teacher-champion. These teachers are so interested in the technology that they develop and maintain the school home pages themselves. Generally, the pages are very well presented and are a glossy brochure for the school.

The second category consists of home pages created mostly by students. These home pages tend to be more erratic - the look-and-feel is inconsistent, some links don't work and there may be some negative comments about the school. However, in our opinion, home pages in this category are produced by schools where the students are encouraged to get involved, where they have access to the computer facilities, where user-driven learning is employed and where free speech is promoted. Certainly, having their work put on the Web for relatives in Australia and Canada to see is one of the greatest encouragements a student could have.

School home pages are excellent vehicles for marketing of the school to parents, boards of governors and the Department of Education. Teachers should think carefully about the type of school they want to portray. In our view, a school should focus on what its students are doing, not on what its teachers are doing. We believe that the school's Web site should reflect this.

3.2.3 Communication

Aside from the Web, the schools have access to E-mail and video-conferencing. These facilities have great potential for improving the schools' ability to communicate with the outside world.

For example, one of the schools has used E-mail to good effect in an EU-funded project called Energy (*http://www.psn.ie/projects/energy/index.html*). The project involves schools from seven countries and its goal is to study electrical energy usage in European households. Students collect the data in their homes and communicate the results to the other members of the project by E-mail. It is hoped that the project will promote increased inter-cultural awareness and knowledge of modern communication techniques.

This type of collaborative project exposes students to influences that they would not otherwise encounter. Since Ireland is an island, few Irish school children have been to two other countries, let alone six. Different cultures can best be appreciated by experiencing them. There is only so much that can be picked up from a text book. It is only via the close contact facilitated by telecommunications technologies that this sort of exposure can be achieved in a cost-effective manner. In this type of project, students learn, not only about the stated project topic, in this case electricity consumption, but also about the world in general.

However, interaction between schools must be given a *raison d'etre*. One of the reactions which we encountered when trying to promote the use of E-mail and video-conferencing was the comment: "Well, why would we want to talk to other schools?". Teachers are used to giving a solo performance in the classroom. They must clearly be shown the advantages of introducing new influences. The kids also need an ice-breaker - a common purpose with the other students - something to get them talking. Once they have started it can be difficult to stop them. Also, the regularity of communication seems to be important. A once-in-a-while approach engenders a careless attitude, while an everyday approach creates a sense of anticipation.

Furthermore, communication is a two-way thing. It is up to both parties to put in the effort. This pressure weighs particularly heavily on the shoulders of the already over-burdened school teacher. More often than not, the teacher's principal will view these projects as extra-cirricular activities, to be added on at the end of the school day. Projects such as these should be integrated into the day-to-day activities of the school. Teachers who are sufficiently motivated to get involved should be encouraged by being given time to contribute, not penalised by being over-worked.

3.2.4 Summary

There were two main conclusions drawn from the first phase of the project.

First, practical issues are uppermost in the minds of Irish teachers. Computer technology is expensive and is not well funded by the Department of Education. Schools pay peak rate prices for the use of phone lines. Even if the school has a computer and modem, creating easy access for students is a problem. Most schools do not have a dedicated computer room. Thus, teachers are either forced to bring the computer to the class on a trolley and trail a telephone cable down the corridor, or have to bring the students to the principal's office in order to use it. The former makes it difficult for the teacher and the latter is hardly conducive to the free expression of the students' opinions.

Second, we found that once these practical issues have been solved, as for the teachers involved in our project, a number of conceptual issues became important. Teachers are faced with a new teaching tool. They have been given little or no training in how to use it successfully in the classroom. The problem comes down to the individual. Some tackle it with vigour and are successful, usually after a few false starts. Some give up and try to ignore it. Still others, view it as their personal toy - something too valuable to share with the students.

4. Phase 2 "Enabling The Educators"

4.1 Approach

In phase two of the project we decided to address some of the conceptual issues on a national basis. To this end, we undertook three initiatives designed to promote usage of the Internet in Irish schools and to help teachers apply the technology in their classroom. The three initiatives were as follows: to develop an educational Resource Site on the Web for Irish Teachers, to commission a free booklet for teachers entitled "A Guide to using the Internet in Irish Schools" and to produce a free poster on the Internet aimed at school children.

4.1.1 A Resource Site for Irish Teachers

One problem frequently encountered by teachers new to the Internet was the question of where to find anything useful. As we all know, the Web can be intimidating and finding a useful piece of information can be like trying to find a needle in a haystack. The Resource Site we have developed is designed to be a first port of call for teachers who are searching for useful material (*http://classroom.broadcom.ie*).

The site was developed by two secondary level students who were employed by Broadcom over the summer holidays. The students had some prior experience of developing home pages and quickly adapted to the Broadcom working environment. Their work included developing HTML pages, writing CGI scripts and setting up mail servers. With little direction from the permanent staff, they have produced a site which is both professional and functional. In our opinion, the site is an excellent example of what school students can produce when they are motivated and empowered.

The site includes:

- a library of links to educational resources on the Web categorised by subject
- a map of Ireland which can be "clicked" to retrieve a county-by-county listing of on-line schools
- a system for teachers to develop on-line worksheets
- information on useful Internet tools, such as IRC, Usenet
- home pages for the three schools in the project
- an on-line version of the Internet guidebook
- a guest book and a mailing list

Eventually, our intention is to hand the Resource Site over to an Irish educational body who will maintain it on an on-going basis.

4.1.2 A Guide to Using The Internet in Irish Schools

Since the booklet was to concentrate on the conceptual issues of using the Internet in education, rather than on the technical issues, it was decided to engage the services of two teachers with practical experience of using the Internet in their classrooms. Although it contains information on how to get online and how to use the Internet, the focus of the text is on how it can be used effectively in the schools. The booklet is full of examples of how the Net can be incorporated into Irish school life.

The booklet includes:

- an explanation of the Internet
- subject-by-subject examples of how the Internet can be effectively employed in schools
- case studies of how teachers involved in our project have used the Internet
- a guide to getting on-line and using Internet tools, e.g. Web browsers, E-mail, FTP

4.1.3 A Poster for Irish School Children

The poster is designed to encourage and motivate schools kids to use the Internet. It provides a brief explanation of the main tools and gives an Internet Timeline to help students understand its history. Also included are screen-shots of the Broadcom Resource Site and of the Irish Times site on the day Michelle Smith won her fourth medal for Ireland at the Atlanta Olympics.

4.2 Findings

The reaction to the three initiatives has been extremely positive. The project has been featured on national television, radio and newspapers. The Resource Pages have been accessed from over 5,500 distinct hosts in 50 countries and we have had over 2,500 requests for the booklet and poster. We have received encouragement, thanks and congratulations from teachers in Ireland, Norway, Sweden, Canada, and the USA: "It's great to see the resources available", "The way of the future", "Keep up the good work", "A very welcome development".

5. Phase 3 "Long Term Research"

Our goal for the final phase of the project is to examine some of the longer term issues involved with the application of telecommunications technology to education. Although this phase of the project has not yet started, the approach that seems most appropriate is to fund educators who will conduct the research and to supply the technical support and expertise ourselves.

6. Conclusions

We have drawn a number of conclusions from our experience working with educators on the introduction of Internet technology to schools in Ireland.

First, appropriate training for teachers is essential. The move to Internet-enabled teaching involves a paradigm shift in educational methods. Teachers must be taught how to subsume the new technology into their teaching techniques and must be shown how to get the best from the facilities and the students. Clearly, training such as this is expensive to implement. However, any investment in computer technology is pointless without it.

Second, to get the most from any telecommunications technology, the user community must have a common purpose which will drive their interaction. Without a rationale and the commitment of the parties involved, the dialogue quickly becomes redundant. In our opinion, national and international educational institutions have a role to play in facilitating and developing this communication. In particular, the European Union has much to gain in strengthening the cultural links between students within Europe. We are headed for an integrated Europe, Irish children must see themselves as part of it.

Third, technologists can only assist educationalists in applying information technology to schools. It is up to the educationalists to solve the educational issues.

Finally, educating our children in the use of technology is essential for the future economic well-being of our nation. Ireland missed the Industrial Revolution, it cannot afford to miss the Information Revolution.

Abstract : The paper describes an aid system for the decision of investment in computerized training, named ECONOF. It is an application software based upon a multicriteria model. It is dedicated to the decision-makers within business. ECONOF helps them to determine the economics of investing in a computerized training program. The development of ECONOF needed a prior judicious criteria choice as well as a particular criteria organization. Each criteria proposed by ECONOF was found within the literature. Examples of criteria are provided in the paper.

1. Introduction

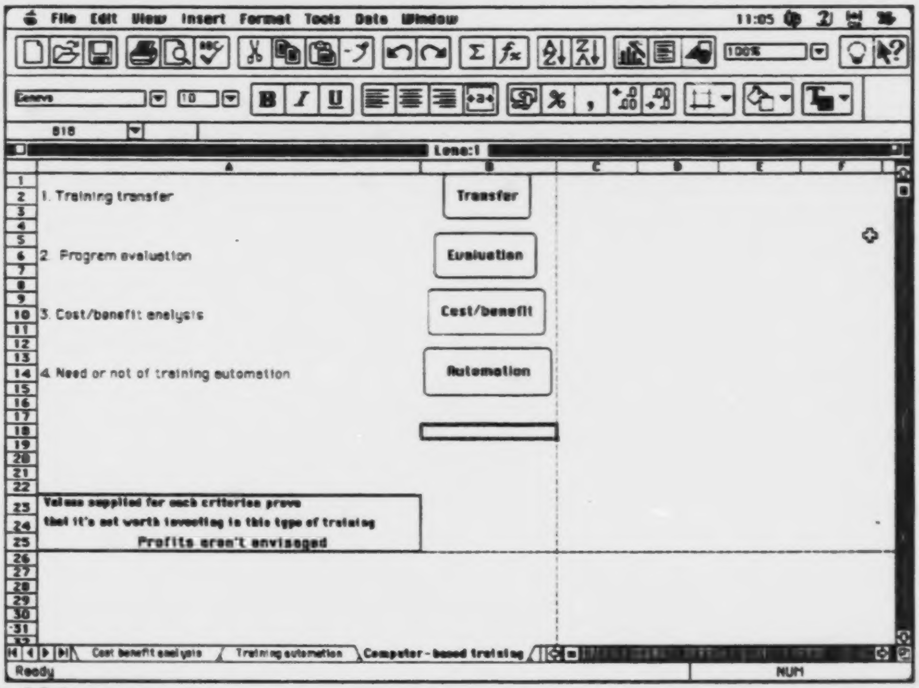
In a time where the world economical situation is going from bad to worse while in the same time, the technology evolves on a daily basis, much interest is focused on the economic aspects of computerized training. Nowadays, an organization which wants to get an important share of the market, considering markets on a world-wide scale, must turn to the training part. Consequently, an organization is led to manage its intellectual investment [Caspar and Afriat 1988] [Davis 1992] [Kelly 1994] [Toffler 1992]. It must also actually benefit from learning and teaching technologies.

The use of technology in training presents many advantages. Among them, [Maginn 1987] mentions the following: "Probably the most encouraging research finding involving individualized instruction from an economic point of view is that use of this medium saves a great deal of training time-sometimes up to 50 percent. And, these time savings translate into redirection of man-days for both students and instructors. Put another way, less training time means less time away from the job". Other advantages mentioned in the literature are: timetable flexibility, equipment portability and being able to ensure continuous training. The use of technology in training can constitute an investment of great significance. Therefore, any administrator, before establishing any form of computerized training, must be able to persuade himself or herself, somehow, that the decision in progress will constitute a crucial contribution to his or her organization. An example of such a decision can be found in [Robinson and Robinson 1990]: "Supervisors justifiably had put employees on probation 48 times; 20 of these employees eventually left the organization. Because rehiring and retraining for the 20 open positions had been costly to Homespun, the company hoped that a training program might reduce the expense".

The aim of the study described in this paper was to provide an aid system for the decision of investment in computerized training. The aid system is named ECONOF. It is essentially an application software developed according to the precise situation of deciding to invest or not in computerized training. The aid system ECONOF is based upon the multicriterion model concept and is essentially built on consequences that different actions entail. It relies on the balancing criteria method summarized in the second part of this paper

[The balancing criteria method] and then, needed a prior judicious criteria choice as well as criteria organization in what is called themes (consequences clouds). Each criteria proposed by ECONOF was found within the literature. Consequently, the proposed multicriterion model takes four themes into account. Those themes were defined after analyzing the specialized literature such as : [Adams 1993] [Campeau, Olfman, Sei and al. 1995] [Coppolino 1986] [Davidove 1993] [Fitzgerald and Cater-Steel 1995] [Garavaglia 1993] [Montebello and Haga 1994] [Nasman 1989] [Ryan Nelson, Whitener and Philcox 1995] [Shelton and Alliger 1993] [Solomon and Templer 1992] [Tannenbaum and Woods 1994] [Zemke and Gunkler 1985].

The ECONOF's themes are: training transfer, program evaluation, cost/benefit analysis and need or not of computerized training. They correspond to the main menu presented at [Fig. 1].



1. Training transfer

2. Program evaluation

3. Cost/benefit analysis

4. Need or not of training automation

Values supplied for each criterion prove
that it's not worth investing in this type of training
Profits aren't envisaged

Figure 1 : Main menu.

The aid system ECONOF takes different criteria into account through actions and situations choice proposed to and selected by the user. Each user's choice corresponds to a weight. A total is then calculated. We insist on the fact that each criteria, action, situation or consequence was established after analyzing the specialized literature. As example, [Zemke and Gunkler 1985] wrote: "The discussion can cover a number of topics: What the training will cover; why the trainee was chosen to participate (or was okeyed for participation); why the training is important to the trainee and to the organization; the supervisor's assessment of the trainee's strengths and weaknesses as they relate to the content and objectives of the program; specific projects or problems related to the content and objectives of the program that the supervisor would like the trainee to work on during the training sessions; and how the supervisor will help the trainee apply the new skills and knowledge when she or he returns from training". Several criteria are listed in this citation.

From the total, the system ECONOF generates an interpretation according to the treated theme and, it's once total interpretations of each theme are got that an interpretation that synthesizes those of all themes is performed. Finally, it's that interpretation synthesis that suggests, to the user, the decision to make, i.e., whether the decision of investing or not in computerized training is a profitable or not profitable decision. That is expressed in term of profits in order to help an administrator in her or his decision about a training program before it is done.

2. The balancing criteria method

When a decisional context is characterized by a great complexity, this method is useful because it guides the intellectual progression, putting each factor, each relation, in a structured system of thinking. There are diverse methods for deciding more rationally. Nevertheless, they all refer to a process in five stages being :

1- to identify, choose and define the aimed objectives. To formulate them in terms of operational criteria measuring the attended results. To allocate a relative importance to these diverse criteria (the criteria column at [Fig. 2]).

2- to look for and to delimit the field of solutions or strategies, i.e., to make a list of possible actions that can contribute to the solution of the encountered problem (actions in the instructions column at [Fig. 2]).

3- to identify the situations that can be envisaged or variables that can modify the result of envisaged actions (situations in the instructions column at [Fig. 2]).

4- to assess the action consequences according to the situations. This is establishing the "points" category that will be considered in the model (the choice column at [Fig. 2]).

5- to evaluate the optimal strategies comparing the way that the expectable results of each of them satisfy the valued criteria, and to select the appropriate action retaining the one that has the greatest chances to result in pursued objectives achievement (the points column at [Fig. 2]) and the subsequent total and interpretation (an example is presented at the bottom of [Fig.1])).

	A	B	C	D
1	Criteria	Instructions	Choice	Points
2				
3	skill and effectiveness transfer	The trainee will, within the scope of his job, use a- immediately what he learnt b- at the latest in 3 months what he learnt c- at the latest in 6 months what he learnt d- never what he learnt		
4		The trainee will, within the scope of his job, use a- everything that he learnt b- a great part of what he learnt c- half of what he learnt d- a small part of what he learnt e- nothing that he learnt		
5	CBT content has been thought to mind to improve trainee productivity	a- quite b- for the major part c- most of the time d- not much e- not at all		
6	behaviour change longevity	The supervisor thinks to use a- a positive approach b- any approach c- a negative approach d- no specific approach		
7	methods used for the training course	The CBT presents a- a lot of examples b- an average number of examples c- a little number of examples d- no example		
8		The CBT presents a- a lot of analogies b- an average number of analogies c- a little number of analogies d- no analogy		

Figure 2: Extract from the training transfer theme.

The balancing criteria method that is used in ECONOF is useful in the case that many objectives are pursued at the same time and one another independent. The resultant criteria are numerous and it takes to balance them to look for the optimal solution, at least if there isn't a best solution than the others on all the plans. One

BEST COPY AVAILABLE

will then retain one solution that allows at best to reach at least one's main objectives in a satisfactory way, although it may mean to do some sacrifices. So, the fact of allocating to criteria definite weights and definitely fixed makes things easier. The usefulness of that method is explained by the fact that complex decisions are usually multicriteria. That means that the decision-maker has many reference values to judge the diverse solutions between which she or he has to choose.

3. A few criteria

The decision aid ECONOF can help provide a structured way to look at issues involving the trainees and the corporate climate. It isn't intended to help the design of a particular computerized course neither to serve as a guide for matching the content of the training course, i.e., the actual learning objectives with the best possible instructional medium. The multicriteria model summarizes a number of key considerations that are generally true of computerized training and are represented by criteria organized into themes. Criteria are the translation, under an operating form, of the identified objectives and constraints of a particular business.

Before explaining some criteria, the aim of each theme will be given. For the theme of training transfer, ECONOF checks if the transfer is done at the time of the training course. The theme of program evaluation evaluates if immediate instructional objectives are reached. The cost/benefit analysis theme sets the link between the investment in training and the accomplishment of specific business objectives up. At last, the training automation theme that complements the cost/benefit analysis and helps see if the computerized training is indeed the best way to decide a particular training project. Now, some criteria taken in any of the four themes will be listed:

- From *training transfer* theme -> criteria *skill and effectiveness transfer*: (top left at [Fig. 2]) or criteria *methods used for the training course* (bottom left at [Fig. 2]).

- From *program evaluation* theme -> criteria *training cost evaluation*: one aspect to assess that corresponds to the instruction column is: *Present trainees productivity in regard to tasks that are taught by computer.*

- From *cost/benefit analysis* theme -> criteria *elapsed time between training course and new knowledge use:* one example of aspect that corresponds to the instruction column is: *It's anticipated that trainees wait after their training: A) Not at all; B) A little; C) Some; D) A long time.*

As mentioned before, for each theme, there are criteria. Criteria correspond to actions or situations stated in the instructions column. Those actions or situations have assigned points category. For example, a positive action or situation for the business might worth 10 points while a negative one might worth 0. When the decision-maker has completed the assessment of a theme, points are added. For example, when the total in training transfer theme is less than 90, ECONOF will advise her or him that the training is at risk to fail in regards to the training transfer. There is a total calculated for each theme. Then, ECONOF takes all these totals to produce a global interpretation. An example is shown at the bottom of [Fig. 1] : the result of the analysis ECONOF made in regards to values supplied for each criterion prove that it's not worth investing in this type of training. Profits are not envisaged. Note that some of the point values can be modified to reflect one's own organization's circumstances. For example, if managers' past experience with computerized training has been truly awful, one might use negative points for that consideration rather than merely assigning no points. When point values are changed, ECONOF will ask for compensating before proposing any comments on the partial and final totals.

4. Conclusion

Training is pervasive, expensive and strategically important. The spread of new technologies depends on their fit with work context, knowledge about the technology, technological infrastructure, and community beliefs about the technology. So, decision makers need the help of decision aid systems to reduce training investments and increase training effectiveness. The result of this decision aid is to help decision makers to make the right choice in regards to invest or not in computerized training. The system ECONOF gives for each theme only two possibilities: that of implementing computerized training and that of not but adds to our understanding of many aspects of it. However, even more research attention needs to be focused in the future on the possibility of giving more than two suggestions to the decision makers, on the areas of computerized learning rather than training, transfer of learning to the workplace, etc.

Abstract

Abstract: Teachers are often forced to be received knowers in implementing technology because of institutional or government directives. Four of us have been engaged in an ongoing conversation that has re-affirmed the importance of fostering communities of connected knowers where dialogue enables us to personalize our knowledge within our working contexts. Our immediate community includes two teachers, a principal, and a university instructional designer. From our conversations, we have written our stories of how we are making sense of technology in our work. Although told individually in this paper, the stories are lived out in a collaborative learning community where we grow and learn from each other.

Change theory proposes many models for successful development and implementation of new educational practices (Fullen, 1991). While acknowledgement is given to involving teachers as active participants for successful innovation and planning (Fullen, 1991; van den Akker & Plomp, 1992) we have also come to realize that changes can cultivate new ways of seeing ourselves as teachers and learners. We as teachers may be seen to implement and/or affect changes, but, how do these changes alter our personal/professional landscape? Moving into new territories with technology has offered us an opening for enrichment of this landscape.

Our recent work at our school in opening up possibilities for our children has launched a philosophical conversation. Technology has become not only a tool by which our students may pursue new learning possibilities but also a vehicle by which each of us is alerted to our basic personal beliefs and fears about our work. It is also a means by which we are pursuing new ways of seeing ourselves as learners/teachers, composing new stories of collaboration with each other and our students. Each staff member has carved his/her own path and yet, many shared dreams have

BEST COPY AVAILABLE

emerged. Anderson (1995), Kazlauskas (1995), and Schuttloffel (1995) have offered possibilities and models for successful implementation of technology. We would like to take these one step further and offer the stories of implementation of technology at our school as portraits of personal and professional growth within a collaborative learning community.

This paper includes highlights of the history of technology implementation at our school. In particular, four of us have met to discuss our own journeys: one as a special education support teacher (Kathy), another as a grade two teacher (Kathleen), a third as an instructional design consultant with the University of Alberta (Katy), and, finally, a school administrator (Laurie). Each of us has a different story of how technology has become part of our lives. Our current school context is the thread that connects us. Through our stories, we hope to share insight into the complexities of life in schools, particularly as it relates to our personal/professional growth with technology.

Kathy's Story

In the past decade it seems that we have been bombarded with new technology tools and programs. The media hype and the excitement that technology innovations have caused in the outside world have made us very anxious to get involved and try out these ideas with our students. While I can see the usefulness of these tools, I continue to ask questions about the change in my pedagogy that technology demands.

Do computers save us time and effort at school? Definitely not at the beginning of their implementation. In fact, quite the opposite is true. I have spent hours learning, experimenting, failing, and trying different programs and tools. However, once I have successfully used a program and integrated it into my planning and my students' days, it is hard to imagine what I ever did without it.

The most significant change in my job has come from my own use of technology. It seems like the computer has crept into every aspect of my teaching from test management and student records to worksheets and activities. I have learned to use a very limited amount of what we have available and keep looking for time to learn, practice and experiment with other tools.

I think that using computers depends largely on your comfort level around this machine. The only way to increase that comfort level is to use it and the only way to use it is to find the time to try. Yet, unless we trust that this will someday make life easier or that technology is important to our students' learning and to our teaching, we will never allow ourselves the time to be the learner.

When I first started using computers I thought this would be the answer to the massive amount of record keeping that goes with my job. I started to record (painfully) on floppy disk, all of my objectives and units from my special education curriculum. Needless to say, this was like the never ending story. Long before I ever found the time to finish my project, the technology had changed to the point that I could no longer used the disks that I had created. Although this was a time consuming endeavour, it was also a wonderful learning experience and greatly increased my comfort level with computers. However, it makes me very cautious about what we are spending our time and money on at our school. I also spend more time thinking and debating the value of programs or new innovations.

Kathleen's Story

I grew up in a home where technology showed very little of its rapid growth. It wasn't until I entered university in 1975 that my mother finally put away her old wringer washing machine and bought an automatic washer. A microwave did not follow until the late 1980's, and only in the last few years has a VCR invaded my mother's home. There are still no signs of a dishwasher, and computers and computer language is as foreign in that home as a far away exotic language would be.

As a child growing up in this setting, I inaccurately determined that technology must be quite dangerous, and something to be avoided. After all, my mother was a teacher, and if it was a good thing, I felt sure that she would be making use of it. Only years later, looking back, have I come to the realization that finances were the real reason that technology was so slow in entering our home. I took my misconception with me to university. While some technology was available to students in the library, I never made use of it.

Eight years ago, technology was introduced into the school where I teach. Classrooms received computers and heavy inservicing followed. The computer was to be used mainly as a way to strengthen students' skills through games. I strongly dislike games, and so now I had two reasons to dislike technology. Firstly, I still saw it as a danger, and secondly, it was another medium for playing games. (This focus has since changed. Computers are now more often used as tools for writing stories and reports, and more recently, for researching.)

Luck was with me, I thought, as I was in a position teaching music and physical education and neither course involved computers. I hoped that no one would notice my absence from the inservicing. On those nights I ran from the school as quickly as possible, trying to mingle with parents who had come to pick up their students.

Shortly after this year of computer introduction, I was assigned a grade two classroom complete with a computer, and a stack of disks. For a few months, the computer sat shrouded in the corner. Then, finally, I decided that the students should be able to use it for drill and review, and I learned the basics from other staff members. To anyone looking in, I would have appeared comfortable with technology. However, other than turning the computer on and off, I still had no connection with it.

Technologically speaking, those were difficult years. I had come to realize that I had incorrectly assessed technology as a child. However, it still frightened me. At the same time, I felt like the rest of the staff had climbed on to a locomotive, and I had elected to stay behind at the train station. I began to doubt my abilities and felt that I had very little to offer the teaching profession. I was not connected to my technological peers.

A year ago, Katy, an instructional design consultant from the University of Alberta came to our school to inservice us in technology. At the beginning of the day, I felt as if we had been transported to another planet. The newness of the technology that Katy showed us overwhelmed many teachers who were comfortable with the technology in place at our school. It left me speechless.

Katy showed us how to use the internet and e-mail. Even though we had some problems using the internet that day, I became intrigued with the communication possibilities that were being opened up to us. Coming from a small rural area, it is often impossible to make connections with a lot of people who can broaden and intensify our learning. Katy was offering us a door to the entire world. Within weeks, I was closeting myself daily with the Internet. Teaching became alive as my grade two class and I researched animals and countries for classroom projects. I e-mailed with a passion.

I began to take my students to the lab for very basic keyboarding. As they absorbed my enthusiasm, they became relaxed and comfortable with technology. Some of the weakest students have flourished, finding great success in our lab, where we are all on a fascinating journey of discovery.

For myself and my students, technology is building a bridge across the distance of rural living to people all over the world. Like chefs creating new meals, we are creating new connections, becoming open to new ways of learning. Our circle of communication grows daily. Personally, I feel recharged as I once again assume the role of both teacher and learner, moving toward the next century with enthusiasm and anticipation.

Katy's Story

I was invited to enter the process of school-based technology planning in the way that I have always come to the

BEST COPY AVAILABLE

practice of educational technology - through relationships framed by the personal. Relationships are the social context in which I design and in which I am able to best explore, and share the experience of technology in my work. I do this through conversation.

I had first worked with Laurie, the principal of Rocky Elementary, on a videodisc project in teacher education. The project belonged to the content expert, a professor in Elementary Education, and Laurie was his graduate student assistant. I was the instructional designer. Through the conversation-based process of design Laurie and I created a social space in which the design process became a process of sharing teaching and personal experience. We became friends and, through that relationship, colleagues and design partners. Laurie knew, and had helped me write, my story of becoming a multimedia instructional designer.

Like so many of us who call ourselves Instructional Designers, I have an experiential base to my practice which only later (and only sometimes) seeks validation through formal training and credentials. Personally, I seek authorization to do what I do - to be, in effect, the expert - through the tacit agreement of my work partners. I enter into their worlds and make my own understanding of technology accessible through talk about experiences with teaching and technology. Self-taught, like they are, I chose a technology model because I had an instructional need best solved by technology-enabled instructional strategies. I did not fall in love with technology as an entity. (That came later). I know that teachers, and university professors, will only approach technology through needing to solve a problem and sharing stories of their solutions and the related tribulations with other teachers who have already been there.

I was invited to an inservice at Rocky Elementary as an Internet expert. Far from being impatient with the resistance to embrace a mostly ubiquitous technology because "what if the network goes down in the middle of the lesson", or becoming defensive about the reliability of 1996 technology, I told the story of my own confrontations, as the technology expert, with constantly failing technology. I entered into the world of the classroom teacher who cannot afford to problem-solve a failed Internet connection for even five minutes with a class of restless 7-year-olds, and worked with the assumption that technology will fail, and how we can recover from that. In the afternoon, I was invited to model my practiced serenity in the face of technological havoc as the school network went down and stayed down all during my hands-on workshop. And I'm told that in so doing I brought the teachers, feeling immensely relieved, into my world of sometimes uneasy alliance with technology for teaching.

Laurie's Story

In 1994, I thought I knew about technology, or, at least some of the possibilities that technology could offer our students. I had embraced it as part of my own classroom teaching since 1980 and had been very active in professional development related to technology. My journey at Rocky Elementary since 1994 has taken me to places I could never have imagined. I have been a privileged observer and participant in a wonderful journey of discovery as I have watched new relationships evolve through dialogue and debate about technology. These relationships have been the foundation for support as teachers have wrestled with the frustration and excitement that technology can bring. Conversations continue spontaneously in the hallways during and after school, at inservices, in our meetings for our technology plan (involving para-professional staff and parents), and now in our writing about our experiences. For us, planning for, and utilizing technology has become another starting point for reflection.

When I came to the school as the principal in 1994, I arrived at a place where many teachers were using computers in exciting ways in their classrooms. For others, computers remained under covers, unused in a corner of the classroom. How could these teachers begin to see themselves as part of the dialogue about teaching and learning with technological tools? In their resistance, I sensed their feeling of being left out and apprehensive about the time that technology could demand of them while at the same time being reluctant to open the doors to new possibilities. Computers had been a mandated part of life for grades four and five teachers for several years with support provided by a teacher (Karen) who was given a portion of time (.2) for technology. I looked for cracks in the doors and tried to provide as many places and spaces as possible for dialogue about changes.

BEST COPY AVAILABLE

Many doors opened through the broadening of our technology planning process. Whereas Karen had done the majority of the planning until 1995, an increase in the decision making authority of teachers through site-based decision making enlarged the circle. Our staff realized that having the authority to determine where and how our budget would be spent also required careful thought and planning. Our first meeting of the "Step-Forward" committee, held in the fall of 1995, had 17 volunteers in attendance (professional staff, support staff, and a parent representative). This committee was originally formed to address changes that we wanted to see in our library, however, we soon realized that it would become our school plan as it related to technology. I found myself as an observer rather than an active participant. A synergy evolved that allowed me to step back and enjoy watching the direction that the group was heading in. The enthusiasm and energy of each member generated exciting discussions about what we should be doing with our technology and how teachers and students would access the support they needed. A plan evolved whereby our new computer purchases would replace the old ones in our grade one classrooms, followed by the twos, and up to the higher grades as we could afford it. We talked about supporting ourselves with professional development and sent eight teachers to a local conference on technology. The group travelled together to the conference and indicated that a highlight was the two hour drive home at the end of the day. The sessions had cultivated new ways of seeing technology for many and the conversations in the van were buzzing with excitement. Shortly afterwards, I watched many covers come off of computers in the corners of classrooms.

An inservice in the spring opened up new conversations as I invited Katy to work with us in our exploration with the Internet. Having worked with her on several other projects, I knew that she would bring another perspective from the University while at the same time understanding the frustrations that we were facing in the classroom. A pre-requisite for the workshop was that all staff members were asked to send an e-mail to Katy and we set up written instructions in the corner of our lab so that staff could complete the task according to their schedules. Those who were comfortable helped first-time users and several overcame the hurdle of delving into the internet through one contact with Katy. During the inservice, our first about using internet, Katy was unable to access a connection for the entire time. Instead of affirming our apprehensions about technology, the relationship that Katy developed with the staff helped to alleviate many fears that people had. She continued talking about her work and the possibilities the internet could offer. In watching Katy, an expert in her field, calmly continue in spite of the technology's unpredictability, a new comfort emerged for many workshop participants. Now it is not uncommon to find teachers at school late Friday evenings, receiving and sending e-mails to new connections they have made all over the world and discovering many possibilities through web searches.

Our Step-Forward committee continues to meet on a regular basis. In making our school plans last spring, and based on the recommendation from the committee, teachers unanimously voted to give up a half hour preparation period each in order to release a half time position more for technology support. With creative budgeting and utilization of our old computers, we have two labs and two technology support teachers. Our grades one, two, and three students can now explore computers in our second lab and exciting new conversations are opening up between young children as they help each other log on, find icons, and weave their way through programs. This has also facilitated exciting new team-teaching opportunities with Kathy as our second technology support teacher. Karen and Kathy have set aside Tuesdays (an hour after school) for drop-in professional development activities related to technology and each session is full.

This journey continues to be two steps forward and one back as we live with the elation and frustrations that technology can bring. However, it has also become one for forging new working relationships with each other and professionals outside of our school. In sharing our struggles with each other we are able to find safe, supportive spaces in which to continue the debate about how best to meet our students' needs.

Possibilities

We, as educators, need to continue to feel success in various areas of our lives. In this way, we are able to experience the success and excitement of learning that we want each of our students to have. Technology in our school is offering educators the chance to experience this excitement. We have a variety of technological encounters available to teachers, and as the requirements are manageable, teachers need not feel threatened by the enormity of technology. Rather, we all have the opportunity to experience being student and teacher as together we work our way along the technological highway.

Our collaborative conversation has led to the development of a community of connected knowers. Communities of discourse, as Tarule (1996) tells us, become sites for promoting and enhancing development. Through coming to a constructed knowing about technology, we situate experiences in the personal domain and therefore, are enabled to translate our knowing into practice that makes sense to us in our work. We envision possibilities instead of enforcing directives, and therefore innovate rather than implement.

Two questions arise from our personal/professional journeys with technology: first of all, is it the nature of technology itself that engages us in dialogue thereby facilitating collaboration? Technology demands dialogue since we are all beginners in many ways. At the same time, there are many threads of continuity for, although it is a new medium, technology does not dismiss the importance of relationships in our work. If anything, it offers new possibilities for broadening collaborative relationships. Secondly, is it that our staff is already on the road to new ways of being teachers/learners and technology just happens to be the catalyst? We would suggest that our growth may be based on a combination of the two; our staff has the opportunity, and is open to engage in reflective conversations about our practice. Technology offers many new landscapes for this dialogue and collaboration.

The Evolution of an Electronic Teaching and Learning Environment

Andreas Brennecke, Ursula Schwolle, Harald Selke

Universität-GH Paderborn, Fürstenallee 11, D-33102 Paderborn, Germany
E-Mail: {anbr | ulla | hase}@uni-paderborn.de

Abstract: The use of new media for teaching and learning is only at its beginning. It varies from multimedia applications for individual learning to different forms of teleteaching. However, learning is an inherently social process and most of our educational activities take place in institutions where students and teachers spend a certain amount of time together.

This paper describes our attempt to support learning by establishing an electronic infrastructure where we can integrate all kinds of materials needed and which is accessible from all places where learning takes place. It turns out that establishing such an infrastructure is a long and tedious learning process itself where didactic, organizational and technical problems are strongly intertwined.

1 Introduction

During the past few years, hypermedia systems have made their way into teaching and learning processes at universities. In most cases, CD-ROMs or the World Wide Web are used to support the dissemination of documents such as lecture notes or background material. While many authors suggest to replace lectures by courseware, we follow a different approach, namely to support socially embedded learning processes through the use of new media. Up to now, documents were only accessible in certain places, such as the university's computer labs or the PC at the student's home, but not in classrooms and lecture halls. Thus, we are far from a seamless information environment where new media support the teaching and learning process throughout.

In this paper we will describe our way towards an integrated electronic teaching and learning environment which we see as an on-going process of implementing technical innovations, using the environment in our daily teaching, exploring new concepts and teaching methods, and evaluating the whole setting. First, we will look at some technical aspects of university teaching and point out problems originating in technical deficiencies. We will then describe, how we started with publishing course material on the World Wide Web and continuously improved the material to an open hypermedia document base which can be worked upon actively by the students. The integration of the material and documents which are created by the students into the courses marks the beginning of an integrated teaching and learning environment where the hypermedia system can be used to support lectures and seminars as well as individual learning. We will report how the technical innovations influenced our way of teaching and how in turn our experiences with the environment determined its further development.

2 Technical Problems in University Teaching

In the sciences and the engineering disciplines at German universities most courses consist of lectures, tutorials, and student assignments. A typical course which students take in the third or fourth year of their studies of computer science at Paderborn consists of four hours per week of lectures in a teaching theater with about 100 students and two hours per week of practical training and discussion (tutorials) in small groups with about 15 students. Additionally, the students have to do homework: Every week they have to accomplish some assignments the results of which are the basis for the discussions in the tutorials; to fulfill the assignments is mandatory to pass the course. Depending on the course, the students' results are marked by the teachers and the students get respective feedback.

Teaching and learning, whether it takes place in universities, other institutions or even as an individual activity at home, are almost impossible without the use of media, the most important being pen and paper. In our western society, pen and paper are in principle available to everyone at any time and any place. Additionally, in university teaching a number of other media are used, mainly to support lecturing. Lennon and Maurer discuss the main problems and advantages of conventional media such as black and white boards, flip charts and overhead transparencies [see Lennon & Maurer 1994]. Two typical problems arise when using complementary electronic media in education: the need to change between conventional and electronic documents and their availability at the different learning places.

The typical use in a lecture is as follows: The lecturers prepare the lessons by browsing through books, journals and other documents such as, for instance notes from lectures they have given before. During the preparation, they either take notes on some sheets of paper that are then taken to class to be copied onto the black board or they type the notes into the computer to prepare overhead transparencies which are presented to the students in the teaching theater. During the lecture, the students usually need to write down what is written on the board or presented on the slides. Slides may also be photo-copied and distributed to the students; however, often they are not available to the students during the lecture so that they cannot annotate them while listening to the lecturer.

Obviously, there are some drawbacks with this kind of lecturing technology. One point we want to emphasize here, is the problem of non-continuity in the use of media: There are several changes between the use of paper or board and the use of electronic material. Preparing hand-outs and disseminating them to the students before the lecture starts, is a step into the right direction.

With multimedia being suggested as the new challenge to university teaching, new ways of presenting material arise. Apart from static objects such as text and images it is now possible to also present animated sequences, simulations and movie clips. To discuss the educational concepts—how to best integrate these new media in a way to enhance learning—is beyond the scope of this paper. However, it becomes obvious that new technical problems arise as well. Students must have access to and work with this material in a way comparable to the way they are nowadays working with pen and paper by, e.g., taking notes and annotating the (multimedia) documents. Lennon and Maurer present a lecture scenario that suggests the use of a hypermedia system "in which there is general and specific information, such as collections of examples and solutions, collections of pictures, video and audio clips, and simulation programs" as the core of lecturing technology ([Lennon & Maurer 1994], p. 9). The use of such a system is only reasonable if the material can be accessed and worked upon not only in the lectures and at the students' workplaces in the university but also at their homes and in the classrooms where students are supposed to play a more active role by discussing their assignments and doing practical exercises. Thus, it is not just a hypermedia system but a whole new infrastructure that has to be created.

3 Technical Changes and Educational Consequences

Our research group on "Computers and Society" started with the use of technical media in education in the summer of 1994. One field of our research is to evaluate the scientific interrelation between information and communication technology and its usage context. One of the crucial issues is to identify how and in what way the overall situation will or can be influenced by changes in the methodical or organizational instruments being employed. In particular, we explore the specific quality of technology in relation to social processes of learning. Consequently, we are testing new technical conceptions in our own teaching practice under the conditions of "Alltagspraxis"; i.e. working under realistic conditions with given time constraints and limited resources in the everyday routine [see Brennecke & Keil-Slawik 1995].

Meanwhile we have organized four courses and several seminars employing specific technical equipment. This has changed from merely providing course material through the World Wide Web in summer 1994 to using an integrated teaching and learning environment in summer 1996. Each step was evaluated [see Brennecke & Keil-Slawik 1995] and respective modifications depending on the results of the preceding courses and the new technological possibilities were made. This can be seen as a process of co-evolution, where the technical environment changes, but also the concepts and practice of our teaching.

In what follows, we will outline the essential steps we took. In the first two courses we used the World Wide Web only. In the second two courses we began to build an integrated teaching and learning environment. We will describe the technical innovations we implemented and the new opportunities created by using the teaching environment. We will then go on to show, how the use of this new technical environment influenced changes in the didactic arrangement and our way of teaching. We will also make some remarks about the evaluation of each step and will discuss the advantages and deficiencies.

3.1 Step I: Using the Web

When we began to use the World Wide Web (Web) in education, the Web was not well known by our students. In summer 1994, only 30% had used the Web before. This figure changed over the last two years, from 72% in 1995 to 78% in summer 1996. In 1996 22% of our students had even used Hyper-G before, a 2nd generation hypermedia system which we use now because of its numerous advantages. Meanwhile, the Web has become an integral part of the students' every day work in computer science. With some time delay, this may come true for other disciplines as well. Hence, it can be said that during the last two years hypermedia systems have turned from a specialist's tool to a widely used source of information.

As a first step we used the Web for providing students with course material mainly consisting of texts and graphics. Apart from the ability to access relevant text pages through hyperlinks from graphical or textual overviews there were few advantages as compared to pen and paper. Students appreciated the availability of the material as well as the ability to always work with the last update. Students had access from every computer on the network of the university and could look for new material, read it on screen or make print-outs. However, since the students could obtain the same material by photocopying it, hypertext was "regarded … as an additional reference resource for conventional … teaching materials". This has also has been suggested by [Whalley 1990].

For the teaching staff, the preparation of the material in the Web meant additional work. The texts were automatically converted into the hypertext format needed, but content-related hyperlinks had to be created manually. Although changes of documents could now be easily accomplished, the administration of the course material proved to be a substantial amount of work. For example, there were no tools for version management, and documents could only be structured via the hierarchical file system. With several hundreds of hypertext nodes this was not easy to handle.

The students could only read the electronic documents in the computer rooms of the university. Our evaluation showed that this environment is not suited for working with text material, mainly because of the noise. There was no access to the documents during the lectures and the tutorials which required the frequent change of media between the electronic documents and paper. Thus the material was not really embedded in the course, students were neither forced to use the system nor were they particularly encouraged to do so. It turned out that at the beginning only 36% and at the end 7% of the students used the Web for reading the documents (for more details of the evaluation see [Brennecke & Keil-Slawik 1995]). This correlates with the experience gained in other projects: that multimedia material with no curricular embedding is rarely used; like, e.g., the system VENE, see [Beran et al. 1995].

Furthermore, the material could only be read. Students were not able to create personal hyperlinks or organize the documents in an individual manner apart from setting bookmarks. Annotations to documents were possible, but only in a rudimentary manner. The browser most widely used at that time, Mosaic, allowed the users to create annotations on a per-document basis in an additional file. With the Netscape browser becoming more prominent, the situation became even worse since this browser does not support annotations at all. As a consequence, it can be said that the Web basically was used as a printing-on-demand device for text documents. Nevertheless, the students gave positive feedback for using the Web although they worked largely with the printed material only.

However, for the teachers it became clear that it made no sense to investigate in the construction of hypermedia document bodies with so little advantages for the students and without a curricular embedding. For the innovative use of hypermedia material we had to do more, but under the conditions of "Alltagspraxis" this could only be done in small steps with an evaluation after each step to show the respective advantages and disadvantages and to get a clear picture of the overall costs.

3.2 Step II: Educational Hypermedia

As a next improvement, in the summer of 1995, we used a different hypermedia system called Hyper-G (now HyperWave [see Maurer 1996]), and additional other electronic tools such as email and news to organize the homework of the students. As compared to traditional Web servers, HyperWave offers several crucial advantages. It has different search facilities, i.e. a full text search is implemented, which is very useful to explore the topics of the lecture and to look up certain key words. Searches can also be limited to user-defined parts of the document space. Single documents or collections may be protected with access rights so that, for instance, only registered participants of a lecture get reading access. This allows us to include documents in the system which we are not permitted to publish in general due to copyright constraints. Beyond that, a private area for each student can be established where he or she can file his or her own documents and create a personal view with links to the available documents. For the teachers the basic advantages lie in the administration of the documents. Without installing real copies, different views can be created. On the one hand, documents may be divided and grouped into different categories such as articles published by our research group, articles from other authors, texts of laws, technical standards etc. On the other hand, the same material may be sorted by the different topics of the lecture. Of course HyperWave offers a lot more features which have been described elsewhere [see Maurer 1996].

At the beginning we had provided articles already printed, theses and reports electronically. These long texts could now be better structured by splitting them into smaller parts, building hypertexts, and putting them into collections, the HyperWave equivalent of a directory, with specific titles. "Semantic maps" were constructed, i.e. different parts of the lecture (e.g. the history of computing) were edited graphically and filed in HyperWave as a "clickable map" such that links referred to relevant documents. The creation of these "semantic maps" is certainly expensive because it needs a lot of design effort, but they are very useful because they give an overview and define the semantic space which is to be explored by the students; the concept of semantic maps has been elaborated by [Klemme 1996]. The references are constructed in a way to point directly to the relevant (text) positions. Thus, the students do not need to browse through the whole universe of documents. Due to these specific advantages of electronic teaching material over paper material the students' acceptance of the electronic material could be significantly increased.

As an additional feature, a special newsgroup was installed to provide a forum for discussions beyond lectures and tutorials. Every week the assignments were sent to this newsgroup, but also published in HyperWave. The students were required to work on these exercises in small groups of up to three persons and send their results via email to the tutors. This was our first experiment with electronic delivery of students' homework. The weekly delivery of homework was mandatory for the students (necessary for certification), therefore they were supposed to deal with the electronic lecture notes in a more intensive way than the year before. The exercises were discussed between students and the tutor and partly presented on the blackboard in a normal (i.e. with no electronic equipment) classroom.

Newsgroups were not an integral part of the teaching environment, and were only used by a few people. Amongst technical notes on HyperWave, there was mainly a discussion about the unfavorable situation of having to read on monitors in the noisy and stuffy computer rooms. This situation could be moderated later by providing a local HyperWave database which the students could take home to their PC's. The electronic delivery (via email) of the students' homework did not bring any specific advantage in this phase of development because it was text based only and there was no possibility for a direct presentation in the classroom. For the discussion of the answers these had to be printed and brought on paper and/or needed to be compiled newly on the blackboard (from memory if necessary).

Since the lectures and tutorials were held in rooms without any computer equipment, neither the material filed in HyperWave could be accessed nor the exercises or home work of the students could be presented. The level of integration was very low and there was a lot of unsatisfactory work due to the non-continuity in the use of media. It became apparent that we had to solve these problems in the next step in order to make more efficient use of multimedia technologies.

3.3 Step III: An Integrated Teaching and Learning Environment

An integrated teaching and learning environment is a technical arrangement that provides the use of electronic documents through all phases of teaching and learning. Without such an environment, new documents can only be used for certain limited tasks and will not be able to unfold its full capacities in supporting teaching and learning. While the technical arrangement alone will not be of very much benefit for teaching and learning purposes and will certainly not revolutionize university education—as has been suggested in popular journals—, we will show that the educational process can be significantly improved if an integrated infrastructure can be provided.

Universal access and seamless integration of various document types needed in a course are mandatory requirements for the technical infrastructure. This means that all teaching material, including the slides used by the lecturer have to be integrated into the hypermedia system and should be accessible from all places where teaching takes place. Images which have been taken from books or other sources have to be scanned and converted into a computer-readable format. Nowadays, most slides are produced on computers anyway. However, as it turned out, integrating these slides into the hypermedia system was not as easy as we had assumed in the beginning. Storing each slide in a single PostScript file would consume too much disk space. Alternatively, it would have been possible to simply store all slides as one large PostScript file. But, a number of problems arise then: On the one hand, the amount of disk space needed is still quite substantial. On the other hand, slides stored in that way can only be accessed in a sequential order; random access to a single slide is not possible. Finally we decided to store the slides in two different ways: first, as a single large PostScript file that the students could print-out to have the images ready at hand without access to a computer and second, as a sequence of GIF images in screen resolution and full color for on-line access. At the beginning, these images were prepared manually until a tool had been developed to automatically convert slides prepared with Powerpoint into a sequence of GIF images [see Bollmeyer 1996].

Homework assigned to the students was also published within the hypermedia system. In addition to the provision of course material, the system was also used actively by the students themselves. For that purpose, every student was given an account on the HyperWave server where he or she could store personal material such as his or her homework. They could also build hypertext pages or copy parts of the course material, thereby creating their personal view. Access rights could be set to allow other users or specific groups of users to read documents or modify them.

The integration of personal and public material proved to be very useful. Now, students delivered their exercises within the hypermedia system and could get direct feedback within the same system in the form of commentaries. This greatly reduced the work that had to be done by the tutors. Furthermore new types of assignments could be given to the students: Some tasks required them to write small hypertexts or to visualize the connections between different bodies of text by putting links between the relevant parts; they were also given design tasks where they had to create a small user interface for a small program.

As a consequence, new ways of presenting the students' homework needed to be found. The tutorials were held in our newly established "electronic classroom", a room initially equipped with a computer linked to the internet and with a number of monitors arranged on low racks in a circle, thus allowing face-to-face communication and cooperation. It was now possible for the tutor to ask any of the students to present their homework. Either the students could walk to the tutor's place and do the presentation from there, or they might stay at their own place letting the tutor turn the pages at their command. It turned out, that most of the presentations, each of which normally takes no longer than five minutes, stirred up vivid discussions where any of the other students were able to ask the tutor to show his or her own alternative solution to the task. The different solutions could then be presented side by side and compared to each others.

We then decided to replace the monitors by PC's, each linked to the internet as well as to an "educational network" allowing us to connect any keyboard mouse or screen to any of the computers in the room. With this technical arrangement, students could do their presentations without having the tutor act as a presenter. It was also possible to give full control over each computer to the students sitting in front of it, so that they could browse through their own homework in order to find some arguments or to access the documents provided by the lecturers as background material for the discussion. With this infrastructure, the way of teaching changed from a teacher-centered style to a mixture of working in small groups, discussing with the whole class and presenting homework. Switching from one working mode to another could be done very easily and thus was done quite often. For instance, some students presented their homework and then small groups of two to three students were given a task where they had to use the course material or some documents prepared especially for this lesson. After some time of trying to solve the task, the results were collected, compared, and discussed with the whole group. Additionally, students were able to access their own document space on the hypermedia system to take notes and store them. However, this was only done on very rare occasions by very few students.

4 Conclusion

We have described some stages in setting up a "learning-supporting infrastructure", using it under everyday constrains of limited time and resources ("Alltagspraxis"), and evaluating the factors of success and failure in order to suggest further improvements. Alltagspraxis is a crucial issue here since we were not interested in proving that something can be accomplished in principle, but rather why and under what circumstances the benefits of new media unfold in daily use.

Our basic premise is that learning is an inherently social activity and that human interaction is a crucial factor for successful learning. Hence, we concentrate on questions such as: What kind of technology is conductive to human learning? Where do technical problems create hindrances and obstacles to effective learning processes? What concepts and teaching methods are needed to make best use of the technology available? It is our firm belief that we can only solve technical problems by providing a technical infrastructure; social problems require social solutions, pedagogical problems require pedagogical solutions, etc. However, separating technical and social problems does not imply that they can be treated in isolation. It is rather necessary to specify more precisely in what way they influence each other, and to avoid misleading expectations about the role of technology in teaching and education.

We first started by using the Web which implemented a sort of printing-on-demand facility. We came to recognize that supporting active learning and obeying certain regulatory constrains such as copyright laws would require us to use a more advanced system. By using HyperWave we could satisfy many of the requirements, but created the demand for a better technical infrastructure. We then built up the electronic classroom just to recognize that simple functions such as writing on-line minutes of discussions, for instance, could not be accomplished unless we were able to shut down all monitors except the one of the person who was editing the minutes. Thus, we were continuously upgrading the infrastructure by adding equipment (educational network) and developing new tools to better integrate different kinds of material.

Besides technical and organizational changes we discovered also that our notions and concepts of teaching changed as well. At the beginning we thought of providing a sort of multimedia textbook. Then we came to recognize that our server included more than 1200 documents of different origins and different quality. Rather than creating a multimedia textbook we were creating semantic maps to allow the students to selectively and effectively explore the universe of documents relevant for the respective lecture. We also had to think about new kinds of work assignments which allowed us to check in an effective way whether or not the relevant documents had been used.

New media may help to develop more flexible forms of combining individual and social learning processes. They may help to develop new kinds of (multimedia) material and cut down costs of accessing and distributing it. It turns out however, that the benefits provided by new technology can only unfold when it is appropriately embedded in a social setting where new pedagogical concepts and organizational settings provide the essential framework for learning.

6 Appendix

The following figures give an impression of the way our technical infrastructure supported the various phases of teaching and learning. The examples are taken from the course "Designing Interactive Systems" which is a third-year course attended by about 100 students. Four hours of lectures and two hours of tutorials are given per week. This particular course has been given for the second time and was held in the winter term 1995/1996.

Figure 1: HyperWave's PC-client Amadeus with the collection overview (at the right side) and some course material (at the left side).

The first figure [Fig. 1] shows a part of the documents we provided for the course as they present themselves when using HyperWave's PC-client Amadeus. On the right-hand side, an overview of the collections of documents can be seen. In this view, these are structured according to the topics of the lecture but other views are available and can be created individually. Among those documents, you will find articles from scientific journals and conferences, the text of certain laws and ISO standards, notes and overviews prepared by the lecturers, as well as slides that have been presented during the lectures. The open collection "Farbgestaltung" (which addresses the issue of how to use colors in the design of interactive systems), contains a number of such slides—one example is shown in the bottom left corner of the figure. Not all of the documents, in particular the slides, are "handed out" at the beginning of the term; the body of material grows from week to week. This is one of the reasons, why CD-ROMs cannot be used in this scenario. In the top left corner of the figure another kind of document can be seen: This is a homework assigned to the students.

The second figure [Fig. 2] shows the view onto some material that one of our students has prepared. In the bottom left corner, you can again see some collections; this is a part from this student's private workspace. The worksheets, here no. 6, are available in hypertext as well as in Postscript format and can thus be easily printed. Within the same collection, there is a picture–shown in the upper left corner. The particular exercise was to find the main problems concerning the use of colors in the application from which this screenshot has been taken. The student's solution to the exercise is given on the right-hand side. The students have linked their argumentation to specific parts of the picture to illustrate the problematic items. It should be noted, that the workspace shown here is in fact shared by a group of two to four students cooperating in solving the exercises. However, every student also has an individual workspace in addition to that. In the bottom line of the collection browser, a document "Punktewertung" can be seen. In this document the tutors give comments to the solution and assign credits. As you might have guessed, that document can only be written by the tutors and is readable only by the students within that small group.

Fehler 1: grelle Farben, die gesamte Oberflaeche ist bunt.

Begruendung: In der Vorlesung wurden eine beschraenkte Farbskala und der Einsatz von zueinander verwandten, gedaempften Farbtoenen empfohlen. Dadurch wird eine bessere Einheitlichkeit erzielt und das Auge nicht so stark ermuedet.

Fehler 2: Verwendung von Rot und Blau direkt nebeneinander.

Begruendung: Dadurch wird das Auge gezwungen, staendig neu zu fokussieren (bis zu 0,5 dioptrien). Das bedeutet eine grosse koerperliche Anstrengung, besonders falls der Benutzer den ganzen Tag auf den Bildschirm schauen muss.

Figure 2: HyperWave's PC-client Amadeus with an example where students have to criticize the use of color in the design of an interactive system.

Having all course material available within the hypermedia system, the problem is that we need an access to that material in the tutorials. There the students' solutions are to be discussed, the background material as well as the slides should be at hand as a reference in those discussions. This is achieved by using the electronic classroom which is shown in the third figure [Fig. 3]. The use of low racks for the computers guarantees that discussions are not disturbed by obstructing the view. Each of the computers can be projected onto the large electronic whiteboard and also onto the other monitors. While the first way of projection allows to focus the students' attention better, the second way is preferred by most tutors because discussions tend to be less centered around the tutor. However, the appropriate method can be chosen by the lecturer at any point in class. In our courses, most of the time in the tutorials is spent on discussing the students' homework, where we can easily turn over the control of the computers to those students who want to present their solutions. Depending on the topic to be covered in the tutorial, we also assign tasks to be solved by small groups during the exercise; the results—sometimes a small hypertext, sometimes the results of an internet search—are discussed in class afterwards.

Hypertext And Semantic Nets: Experiences With Modular Authoring

Eric Brok,
Faculty of Engineering,
Open university of the Netherlands.
E-mail eric.brok@ouh.nl

Abstract: This article discusses the usability of semantic nets in modular design and writing, as experienced by authors in four test projects. Findings show the importance of clear agreement on the semantics of graphical networks used to describe content structure. The choice of semantics also relates to the effort involved in writing node texts modularly, keeping contextual references and transitional phrases to a minimum. Since such phrases can be important in learning however, some directions are proposed to accommodate for these in a modular setting. (Extended version of this paper is on the confrence cd-rom).

Introduction

Computer Supported Hypertext Authoring

To improve the way in which learning material can be revised, re-used and recombined, the Open university of the Netherlands developed ILCE, a computer based Interactive Learning and Course development Environment [Valcke & Vuist 95], [Brok 95]). This current article focuses on how authors use networks to (re)organise modular text in ILCE. For an account of student experiences see [Martens et al. In press].

The ILCE system supports a top-down course design method. Course designers define a *content model* which is to represent the structure of the content matter as a network [Fig. 1].

Each network node represents a certain subject. Also each node has an internal substructure of sections on the subject, like 'example' and 'exercise'. Subsequently, authors elaborate each node section into actual text, graphics, animation or any other type of media clip. Authors assign attributes to each node (section) to specify conditions (e.g. for which type of student the section will be appropriate).

After a repository of learning material is thus produced, the course team can specify a student (population) profile so the system will automatically select an appropriate and consistent subset of node sections. The selected learning material is delivered in printed and/or electronic format.

Hypertext And Narration

An increasingly acknowledged distinction between hypertexts is between narratives and collections (e.g. [Gloor 90]). In an educational setting, we can speak of teacher stance versus discovery stance respectively [Brok & Martens In press]. Since no human teacher is present in distance education (and many computer based training), all coaching of the learning process should be in the material itself and therefore takes on a teacher stance. This has important repercussions for modular authoring.

In discovery-stance hypertexts, separate articles can easily be written by different authors from different perspectives. Moreover, there is no need for a narrative connection between articles. In teacher-stance hypertexts however, the reader expects a well-structured narrative line, in which arguments are gradually developed. The reader also expects the text to speak with one voice, consistent in style and content. These demands are difficult to meet if the presented material is dynamically selected from a broad collection of content nodes.

On the other hand, when authors produce hypertext versions of existing text books, consistent style will be assured, but careful editing will be needed to tailor the texts for highly modular use. Existing material can be hard to use as a basis for publishing customised versions. For large text bases, automated text to hypertext conversion is highly desirable but often results in less meaningful structures than hand conversion [Riner 91].

Relating Hypertext To Semantic Nets

A semantic net [Fig. 2] consists of nodes and links, and is used to express the semantic structure of a certain subject domain. Each node identifies an object (class) in the domain, and the links represent semantic relationship between nodes.

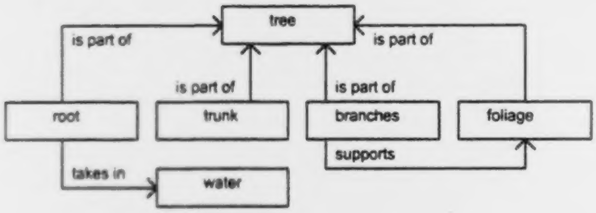

Figure 2: A simple semantic network.

Given the structural similarity between hypertext and semantic nets, it is often proposed that (re)organisation of texts into modular hypertext, should be mediated by defining a semantic net (e.g. [Rada 90]). Mapping semantic nets directly onto hypertext structure is not straightforward however and has been the subject of considerable debate (e.g. [Jonassen & Mandl 90]).

There are some important properties of a semantic network to note. In genuine semantic nets, the meaning of a node lies solely in the relationships with other nodes, not inside the node itself. In hypertext however, the nodes contain abundant subject material; the links serve primarily as navigational aids instead of expressions to assign meaning to the node contents.

Another important property of genuine semantic nets, is that they are not biased to a certain usage, for example the order in which the nodes are to be traversed in a reading or teaching session. This same attribute is claimed to be an important attribute of hypertext but, as discussed, is often hard to realise in practice.

Several interesting alternative approaches were proposed to relate networks to hypertext structure. [Chaoui et al. 92] propose a distinction between structure links and semantic links in their hypertext network. This can be perceived as a way to combine narrative links with genuine semantic links.

[Rada 90] proposes to project hypertext nodes (paragraphs) onto links (node-link-node triples) in the semantic net instead of simply onto nodes. This approach should be very feasible, since each link in a genuine semantic net asserts a certain statement, which is easily elaborated in a textual treatment of that statement.

Semantics Of Content Models

There are many ways to design and interpret a ILCE network which represents study content. Imagine a science course on global heating. [Fig. 3] shows a section of the content model. What does this model exactly *mean*?

- In the domain, after each occurrence of the phenomenon 'a storm', there will be an occurrence of the phenomenon 'a calm'.
- In the course, the subject 'a calm' should always be treated after the subject 'a storm'.
- In the course material, the text called 'calm' will be appended to the text called 'storm'.

Figure 3: 'After a storm comes a calm'.

Note, these interpretations are fundamentally different. The first interpretation takes the model to describe the structure of *the subject domain* itself, regardless the order in which the subject is to be treated in an educational session. In such cases we can speak of a genuine semantic network.

The second interpretation takes the network to describe the structure of *the narrative or educational discourse*. In such cases we will speak of a discourse network. The third interpretation is very related to discourse, but actually refers to specific pieces of learning material instead of concepts. In such cases we will speak of a document network.

The difference between semantic and discourse networks is elemental (e.g. [Wenger 87], p. 13-25; [Lesgold 87], [Chaoui et al. 92]), but in practice, domain structure and discourse structure tend to match. Differences will become apparent however, when network grain is fairly detailed while nodes are elaborated into texts. If the science course expresses the fact that 'a tree consists of root, trunk, branches and foliage', a fairly detailed semantic network would express this fact as in figure [Fig. 4]a.

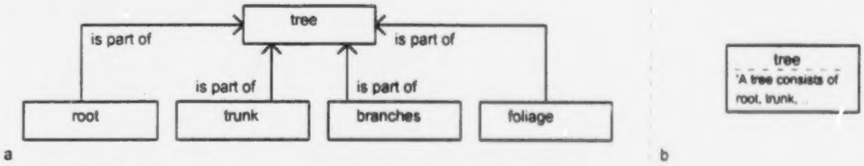

Figure 4: A semantic network (a) and a document network (b) expressing the same fact.

In a discourse or document network however [Fig. 4]b, the same fact would be expressed in a single node, treating the subject 'tree'. *Only when* there are also separate treatments on root, trunk, branches and foliage, there is need for other nodes accordingly. A semantic network needs to be fairly detailed, to properly express all subject knowledge in the network structure. In a discourse network, nodes are only distinguished as far as they will be elaborated into separate treatments.

Since constructing a network based on semantics is a very difficult task for a large document ([Chaoui et al. 92]), such as a book, a discourse/document network approach might be more feasible for organizing large repositories.

Summing up, in semantic networks subject knowledge is represented in the network structure whereas in discourse or document networks subject knowledge is in the node contents. [Fig. 6] offers an overview of this issue.

	network structure	node contents	relationships
semantic network	describes domain structure	none or redundant	e.g. - is a - causes - is above
discourse/ document network	describes discourse/ document structure	describes domain	e.g. - summary of - explains - prerequisite of

Figure 6: Differences between semantic networks and discourse or document networks.

Relationship Types

[Fig. 6] also shows how semantic networks typically exploit other types of relationships than discourse networks. As mentioned ([Fig. 1]), ILCE resolves typical discourse relationships (like 'example of) in the *internal* structure of nodes. So *between* nodes, we would expect a discourse network in ILCE to exploit much less different relationships than a semantic network.

Research Questions

We empirically investigated how authors used ILCE content models to organise educational hypertexts:
- which type of network semantics (semantic/discourse/document) do authors use spontaneously?
- which type of links do they use most frequent?
- how does choice of network semantics relate to easy elaboration of node content?

Method

Test Projects

Prototype versions of the ILCE system were used on an experimental basis in four course teams. Study subjects were law, math, statistics and multimedia. In each team, two course designers/authors used the system to design a content model and (except for one team) elaborated nodes into text. Several hundreds of text pages were reorganised this way, and were studied afterward by students for evaluation [Martens et al. In press].

Procedure

During the first year of investigation several methods were used to gather author responses.
Interviews. Soon after authors had acquainted themselves with the ILCE system, three of them were interviewed.
Plenary meetings. During the year, there were regular meetings in which experiences were exchanged.
Survey. After they had extensive experience with the ILCE system, five authors filled out a questionnaire.
The survey featured about 100 questions, concerning:
- the course development method which ILCE was to support;
- the structural design of the ILCE system as a cognitive tool;
- the technical performance and local user interface details.

This article will only report on questions regarding modular writing and the use of networks.

Results

Appreciation. In general, authors expressed very positive opinions about the structured design method. They stated the system makes them think very systematically about course content and structure, spelling out design choices that would be left implicit otherwise [Brok & Martens In press].

Mixing styles. Our investigation showed, that in practice most authors spontaneously produced hybrid content models, interweaving discourse/document - and semantic structure. Most relationships structure educational discourse; only some exist in the subject domain.

Overall, authors did not run into problems mixing these styles, since discourse structure and domain structure often matched to a large extend. This was probably because most authors converted existing courses. Some relationships could be easily misinterpreted by other authors however, such as 'follows after'.

Relationship types. As discourse networks tend to exploit few different relationship types, authors only used about three types for most of the links.

Hierarchy. To balance larger and smaller nodes, authors tended to organise the network as a tree, with large nodes branching into smaller nodes, as in a table of contents. Note, this was a significant move away from viewing the content model as a semantic network, unbiased to any narrative ordering.

Network semantics and writing. Our main observation was, that nodes in discourse networks were far more easy to elaborate into texts than nodes in genuine semantic nets. One author specifically reported he failed to assign texts to nodes of a fine grain semantic net and changed to a rough grain discourse network instead.

Authors expressed they need to have a specific node order in mind while writing the separate texts. Some found it hard to write on a general concept regardless the context. These authors preferred to write separate texts for each context, differing in perspective but largely common in content. Separating general paragraphs from example applications in existing text books, required much more editing than expected. The original text book also featured cases continuing through multiple subjects, which posed some problems for modular delivery.

Questionnaire Results

[Tab. 1] shows mean scores for item clusters, concerning content model design and modular authoring. Respondents expressed moderate opinions on the ease of designing and editing a content model (*model*). They reported no problems in choosing and assigning relationships between nodes (*relations*). The option of assigning levels (e.g. 'section', 'chapter') to nodes was regarded useful and easy to work with (*levels*). Adding content texts to nodes proved much harder (*nodes*). Respondents expressed modular writing was quite hard to put into practice (*writing*). In response of one overall question, respondents were fairly positive about the course design method altogether (*overall*).

	issue	*number of questions*	*mean (1-5)*	*s.d. among subjects*
model	Ease of designing/editing content model	2	3.38	0.77
relations	Ease of assigning relationships	3	3.64	1.16
levels	Ease of assigning levels to nodes	2	3.88	1.34
nodes	Ease of adding content to nodes	1	2,50	1,29
writing	Ease of modular writing	2	1.75	0.87
overall	Overall positive on the design method	1	3.75	0.50

Table 1: Questionnaire results: content model design and elaboration.

Conclusions And Recommendations

Network semantics. Authors intermingled domain and discourse/document relationship types, with a strong preference for the latter. However most authors didn't report any trouble with these mixed styles, we expect serious confusion when content networks will be used or elaborated by people other than the original creators.

Discourse/document networks proved far more easy to elaborate into texts than genuine semantic nets. Authors welcomed the option to assign hierarchical levels to nodes, such as 'chapter' and 'unit', which explicitly stresses the preference for discourse structure.

Flexible reuse Using a document network (instead of a semantic net) is far from a drawback in itself, but may restrict the flexible (re)use of material. The authors tended to design one fixed learning path, customised by optional and alternate texts. Alternative orderings would call for many adaptations in texts.

Modular writing. Writing is an activity in context. Authors find it hard to write actual texts with little knowledge about the context in which students will study it.

Without narrative transition phrases, like 'thus' and 'as we have seen', students may fail to understand the link between text parts. A possible solution would be to distinguish *link nodes* from *content nodes*. Content nodes should be written generally, to be used as part of any course. Course-specific link nodes would introduce a content node (set) to the student, with a narrative explaining the relationship with prior issues and the role within the course as a whole. This way, students will also accept style and perspective shifts between content nodes.

All in all, we learned it is much more easy for authors to use systems like ILCE as an advanced hypertext document management system, rather than a knowledge representation tool. Nevertheless, computer supported course design, production and delivery was welcomed very positive by the authors involved.

Concept-based Navigation in Educational Hypermedia and its Implementation on WWW

Peter Brusilovsky and Elmar Schwarz
Carnegie Mellon University,
Pittsburgh, PA 15213 USA
E-mail: {plb | schwarz}@andrew.cmu.edu

Abstract: This paper is centered around concept-based navigation, a powerful hypermedia navigation model. Main ideas behind concept-based navigation model are concept-based indexing and student modeling. We introduce the idea of concept-based navigation and describe its implementation in InterBook, an authoring system for designing Web-based adaptive hypermedia. We also demonstrate a number of benefits of the approach itself and its implementation in InterBook.

Introduction

Classic navigation model in hypermedia is page-to-page navigation using links between pages. This paper suggests and describes a more powerful navigation model which we call concept-based navigation. Main ideas behind concept-based navigation model are concept-based indexing and student modeling. Concept-based indexing is used to provide additional information about the content of each hypermedia page by indexing it with related domain concepts. In this context, by domain concepts we mean atomic pieces of knowledge in a given domain. Student modeling is used to represent the state of the student knowledge about domain concepts.

A hypermedia page in a system which uses indexing and student modeling is no longer a black box to the hypermedia server. Indexing tells which pieces of domain knowledge stand behind the page and student modeling tells how well the student is familiar with these pieces of knowledge. This additional knowledge turns a hypermedia system into a knowledge-based system. Including additional knowledge into regular hypermedia pages opens several ways for increasing functionality of a hypermedia system such as adaptive navigation support, adaptive guidance, intelligent help, and concept-based navigation.

We have implemented adaptive navigation support, adaptive guidance, and intelligent help in ELM-ART, a Web-based Intelligent Tutor for LISP [Schwarz, Brusilovsky & Weber 1996]. In our recent system InterBook [Brusilovsky, Schwarz & Weber 1996], an authoring system for designing Web-based adaptive hypermedia we have implemented all the above techniques adding concept-based navigation. This paper is centered around concept-based navigation. We describe special aspects of the implementation of concept-based navigation in InterBook and demonstrate a number of benefits of the approach itself and its implementation.

Background: Indexing in Educational Systems

Indexing was originally suggested in Computer Assisted Instruction (CAI) context by Osin [Osin 1976] who suggested a framework for indexing CAI frames by a set of topics which it covers. Such indexed sets of frames were not related to any pre-scribed order of presentation. They can be accumulated, stored in special libraries, and re-used by different authors to create their own courses. In the multimedia field, a similar idea of a re-usable database of multimedia learning material indexed by topics and keywords is elaborated by Olimpo et al. [Olimpo et al. 1990].

Later indexing was applied in hypermedia and ITS authoring area. In the hypermedia authoring area, an idea of indexing was elaborated by Mayes, Kibby and Watson [Mayes, Kibby & Watson 1988] in the StrathTutor system. They stressed additional preference of indexing the frames of learning material - the possibility to indicate related pairs of frames not by tedious glossary linking of pieces of learning material together, but dynamically, on the basis of similarity of corresponded sets of topics. In the ITS authoring area, indexing was applied to turn traditional CAI into a "slightly intelligent" ICAI [Elsom-Cook & O'Malley 1990; Grandbastien & Gavignet 1994; Vassileva 1992]. "Slightly intelligent" ICAI are based on both the CAI and ITS paradigms.

The teaching material is not generated as in 'orthodox' ITS, but stored in CAI-like frames. However, these frames are indexed with the concepts from an explicit domain model network, so they can be selected intelligently.

The most recent application of indexing on the crossroads of the above directions is hypermedia-based ITS which uses the indexing technology to connect the learning material represented in hypermedia form with the domain knowledge base. One of the first hypermedia-based ITS HITS [Tang, Barden & Clifton 1990] separates authoring of teaching material (creating hyperbooks) and course design. The duty of the course designer is designing a syllabus (a hierarchy of subjects with topics attached to it), to choose the hyperbooks to be used and to specify the goal level of student knowledge (in terms of the student model). HITS will manage the course itself, selecting or suggesting the relevant information and tests from the chosen hyperbooks according the syllabus. More recent hypermedia-based ITS are SHIVA [Zeiliger 1993], ITEM/PG and ISIS-Tutor [Brusilovsky, Pesin & Zyryanov 1993].

Concept-based navigation in InterBook

Indexing

InterBook represents educational material as a set of electronic textbooks (ET). An electronic textbook is hierarchically structured into units of different level: chapters, sections, and subsections. Several ET on the same subject form a bookshelf. All books from the same bookshelf are indexed by the same set of domain concepts. This set of domain concepts forms a domain model for the given subject. InterBook uses role-based indexing as suggested by Osin [Osin 1976]. Each terminal unit has an attached list of related concepts (we call this list *spectrum* of the unit) representing a name and a role of each concept in the unit. InterBook mainly supports two roles: outcome concepts and background concepts. A concept is included in the spectrum of a page as an outcome concept, if some part of this page presents the piece of knowledge designated by the concept. A concept is included into the spectrum as a background concept, if a student has to know this concept to understand the content of the page. These two roles have been shown to be sufficient in many contexts [Brusilovsky 1992; Capell & Dannenberg 1993].

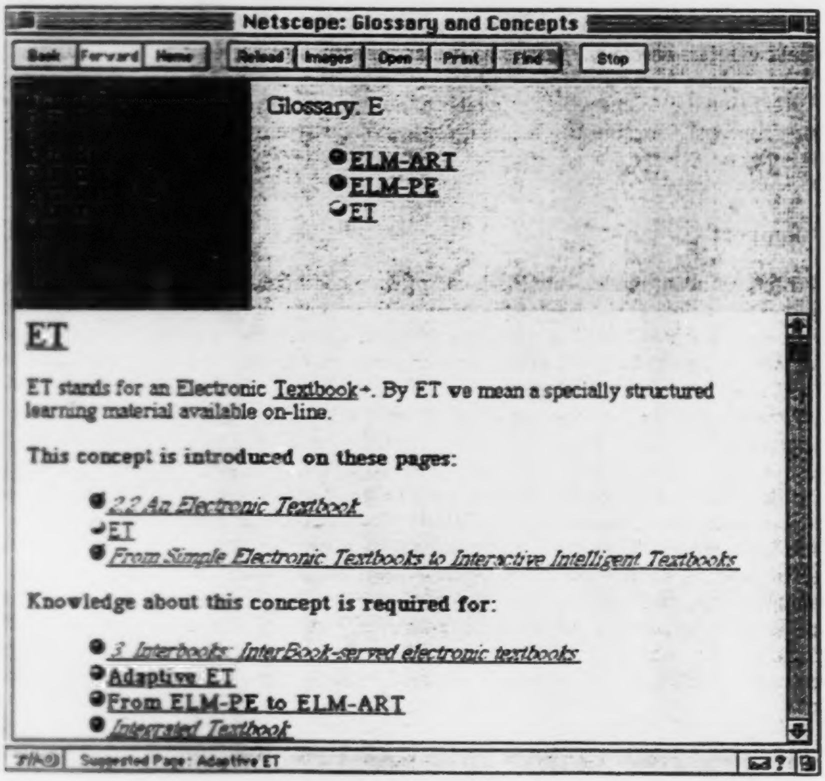
Student modeling

To represent individual user's knowledge InterBook uses an *overlay student model*. For each domain model concept, an overlay model stores a value which is an estimation of the user knowledge level of this concept (for example, unlearned, learned, and well-learned). This type of model is powerful and flexible: it can measure independently the user's knowledge of different topics. Student model and spectrum of a unit can be used to determine an educational state of the unit, for example, is it not ready to be learned (if it has unlearned concepts among its background concepts), ready to be learned (if all its background concepts are learned), or "nothing new" (if all its outcome concepts are well-learned).

The spectrum of a unit is also used to update the student model. When the user completes a unit (either a presentation or testing one) the "knowledge levels" for all concepts of the unit's spectrum are updated. The overall score of total knowledge is computed by adding factors like pure reading experience and passing or failing tests. Structure and algorithms for doing that are not important at this point and will not be discussed here.

Conventional navigation tools

InterBook provides a student with several popular navigation tools such as table of content, search, or navigation bar. These tools are used in a number of electronic textbooks. A specific feature of InterBook is that no authoring of these tools is required: everything is generated by the system. Each navigation tool presents some structured list of unit names which can be user for navigation (naturally, all names are clickable links). Table of content represents a hierarchy of units. Search tool lets a student find all units which contains a specific text. Navigation bar [Fig. 1] shows names of all direct predecessors and all brothers of current unit. It provides an orientation support ("where am I?") and an easy way to move "up", "left", and "right" within the three of units.



Glossary: E

- ELM-ART
- ELM-PE
- ET

ET

ET stands for an Electronic Textbook+. By ET we mean a specially structured learning material available on-line.

This concept is introduced on these pages:

- *2.2 An Electronic Textbook*
- ET
- *From Simple Electronic Textbooks to Interactive Intelligent Textbooks*

Knowledge about this concept is required for:

- *3 Interbooks: InterBook-served electronic textbooks*
- Adaptive ET
- From ELM-PE to ELM-ART
- *Integrated Textbook*

Figure 2: The glossary window displays a short description of the referred concept. Below this description pages and concepts are listed which either require or teach the current concept.

Concept-based navigation tools

In addition to regular navigation tools InterBook provides some concept-based tools. First of all, InterBook is able to construct a glossary of all domain concepts. Glossary is shown in a special Glossary window [Fig. 2] which contains an interface for locating a concept by its name. For each concept InterBook shows its description (if provided by an author) and generates links to all units which has this concept in its spectrum either as a background or outcome concept. In this sense, glossary in InterBook unifies the features of two classic tools glossary and index.

Second, InterBook generates a concept bar for each unit [Fig. 1]. Concept bar shows clearly all background and outcome concepts for the unit. For a terminal unit, these concepts are taken from its spectrum. For a higher level unit, the list of background and outcome concepts is generated from the respective lists of its subunits. The outcome of any subunit is an outcome of the section, whilst prerequisites are only inherited from the subunits, if they are not tought within another subunit of the same section. This mechanism ensures that a student is always able to see the real educational closure of a section. We decided to show background and outcome of a section in two different parts or frames. Outcome and background are scrollable independently to asure fast access of both of them.

Additional links from the text of a unit to glossary concepts are generated based upon the concept names. These automatically generated links point to the glossary window, where the student, as described, has access to other units which deal with that concept. Links to concepts from the text of a unit are annotated according to their role on the current page. Each link indicates whether the marked concept is an outcome concept, part of the background or just a reference to some concept without a certain role. Further InterBook allows for references to other pages, that might appear within the text.

With concept-based indexing, InterBook can build a naturally structured and tightly interlinked hyperspace of educational material, which supports advanced navigation. For example, a student can start from a unit which describes several concepts, then move to a glossary page which describes one of these concepts. If the student still cannot completely understand the concept, he or she can navigate to one of the units presenting this concept (i.e. having the concept as an outcome concept in the spectrum) which provide some example for the concept. Then the student can select one of the problems related with the concept to test the obtained knowledge. If the problem appears to be hard, the student can analyze the list of background concepts in the problem spectrum and move from a problem to the another concept which is not clear yet (and which can be far away in the network from the starting concept). Thus the user has many ways of navigation and many paths going from the current node to related nodes.

Navigation support

With its overlay student model, InterBook can provide additional help to a student in a form of adaptive navigation support [Brusilovsky 1996]. InterBook uses three main ways of adaptive navigation support. First, InterBook shows an educational status of each unit by marking each link to the unit with a colored icon. Each link to the unit is annotated in that way in all contexts where this link is shown: in the table of content, in the search list, in the navigation bar, etc. Different colors and icons represent different educational status. For example, "red" means not ready-to-be-learned and "white" means nothing new. Checkmarks indicate visited pages. The same color is used to indicate the status of the current unit page either by colored bars or colored backgrounds for concepts. Second, InterBook can provide background help on demand by showing an adaptively sorted list of pages which introduce background knowledge of the current unit. These two ways of adaptive navigation support described in more details in [Brusilovsky, Schwarz & Weber 1996].

Third, InterBook shows the user's knowledge level for each concept represented in the concept bar by attaching icons of different size to concept names. No annotation means "unknown", small check mark means "known" (learning started), medium check mark means "learned", and big check mark means "well-learned". Red exclamation marks indicate concepts on which the student recently failed in solving a problem. In fact, what is shown to the student is the state of the student model. Such a technique is usually called visible student model. A specific feature if InterBook is that visible student model is used for orientation and navigation support.

Discussion: Benefits of Concept-Based Navigation

Visualization of indexing

We consider the visualization of indexing as an important technique. Our philosophy of books, chapters and sections having their own internal didactic structure, which should not be broken without any significant reason, lead us to visualize not only the content of the current page, but the content of the current section as well. InterBook provides navigation support not only for terminal pages, but also for books, chapters, and sections. This enables students not only to select page-by-page their own individual learning paths, but also to select larger units like section and chapter that will bring him to his individual learning goal.

We decided to implement some textual visualization in an old-fashioned hypertext style [Fig. 1]. We took into account that those interfaces are less transparent for novices, but the advantages exceed this problem: textual representation in lists take much less space than graphical one. The required space can be even collapsed, since it a quite easy to generate scrollable lists, which, of course, demand some basic skills on the user's side. Additionally textual representation can be easily extended with adaptive visual cues. Last but not least, old-fashioned techniques like hyperlinks are more transparent in usage and better known to more users.

Visualizing state of knowledge

It is important that in InterBook an implicit feedback about the state of each unit in adaptive hypermedia is represented by either adding visual cues to a link to that unit. A student that is looking for a strong support will work perfectly with such summarizing cues. For more advanced users this could be unsatisfying, because the navigation aids on a higher level of InterBook do just provide suggestions, but can't help with reasons for these suggestions. A page may be suggested because it introduces some very basic competely new concepts to the student or because it just talks about some concept of minor interests, whilst all other concepts are already well-known.

By annotating all concepts with adaptive checkmarks the student can gain an overview about the content of each page quicker [Fig. 1]. He or she can notice by looking at the annotations which are the missing concepts for a page or what really new can be learned on that pageand why it might be unnecessary to read it, because almost all concepts are already known.

Visualizing Relationshios between Units and Concepts

The logical next step of visualizing indexing information is taken by showing information about the current educational relationships between units and concepts. Some approaches use orientation maps, which are represented by a graph. These maps show pages as nodes and one or several concepts as edges [Capell & Dannenberg 1993]. Because these graphical ways of visualizing use a lot of space on the screen, they become completely insufficient in very complex learning environments with many sections and relationships.

Again we decided for some old-fashioned way of common hypermedia pages with simple hypermedia links. We put each of the edges and the nodes of the graph on a single page. As we did see in the last section, nodes are given by the text pages itself with visualized adaptive index. By showing the links in the visualized index the student can reach a concept page in the glossary [Fig. 1]. Such a concept page can be considered as an intelligent copy of an index entry in a common printed textbook. It shortly introduces the concept the page referes to and gives links to all pages where the concept can be learned, i.e. it is an outcome of the page, and for which pages it can be useful, i.e. it is part of the background [Fig. 2]. From this page the student can understand how the information flows through this concept. By this two-way navigation system implemented in InterBook the student is not provided with a general overview like in graphical representation, but he or she can follow information flow forward and backward in his or her textbook to understand the didactic relationships of current page and its conceptual environment. We get away from simple visualization of relationships towards real understanding of them, which should be the final goal of any teaching operation.

Conclusion

Concep-based navigation extends functionality of educational hypermedia systems. This approach is based on concept-based indexing and student modeling which show to be relatively cheap and useful technologies for authoring "more intelligent" hypermedia systems. We have described an implementation of concept-based navigation in our InterBook system for authoring Web-based hypermedia and argued for several benefits of this approach. We hope that our ideas will be usefulf for researchers in the field of educational hypermedia and that our tool will be useful for practioners who are interested to extend their hypermedia systems with advanced way of navigation and adaptive navigation support.

What Use Are Reviews? An Analysis of Multimedia Information Software Reviews and Their Relevance to Home Information Consumers

Kathy Buckner, Department of Communication and Information Studies, Queen Margaret College, Edinburgh, UK. e-mail: k.buckner@mail.qmced.ac.uk

Mark Gillham, Department of Communication and Information Studies, Queen Margaret College, Edinburgh, UK. e-mail: m.gillham@mail.qmced.ac.uk

Abstract: Multimedia information systems are a valuable resource for home information consumers. Users need to be able to make informed decisions about the quality and suitability, for their needs, of products which they are considering purchasing. Reviews in print and electronic form are likely to be the primary source of information. This paper examines the relevance of review articles and reports on a study undertaken to assess the criteria used by reviewers when evaluating products. It also compares those criteria with the criteria used by home users when evaluating products which they have already purchased. The development of a transferable methodology which would assist in the evaluation of review information provision in other domains (e.g. schools and libraries) is discussed.

Background

A previous study of home users of information CD-ROM products undertaken by [Gillham & Buckner 1996] investigated user behaviour with these products and examined their perceptions of various evaluation criteria. There were anomalies between the users' stated priorities and their observed actions. The most important stated priorities were dominated by those aspects of using multimedia products which might be seen to be academically related i.e. searching, browsing and accessing textual information. Observations of the users interacting with their systems (which, by the very fact of being observations, may have influenced behaviour) indicated that users actually preferred looking at the multimedia aspects of the information products. Thus, when making decisions as to which information products to purchase users are faced with numerous decisions regarding which criteria are of most significance in relation to their needs. Supposing that users can articulate their need they are then faced with the problem of obtaining information about the products prior to making decisions about purchase.

Because of the nature of new media compared with traditional print sources it is difficult for the potential purchaser to gain an accurate picture of the product. The publishers' marketing information is an obvious source of information but purchasers may regard this information as biased and may seek a more independent opinion of the products. Thus, reviews in magazines, journals or electronic media may be the main way in which information is received about products. To complement our understanding of users' needs and stated preferences the authors have undertaken a further study of review texts.

Relevance of Marketing Information

Advertising material for CD-ROM information products tends to be more limited in the general computing press than that which is available for hardware products. Potential purchasers would have to be fairly focused in their search for advertising information on a particular product. Even supposing sufficient advertising literature was easily accessible we might question the value of this for comparison of similar products. In their advertising literature publishers tend to focus on the perceived motivation of users such as achievement, power, family fun, desire to be accepted, and others identified by [Durgee 1991] in his analysis of Dichter's Handbook of Consumer Motivations (1964). However, there is little evidence that consumers can effectively utilise advertisements in making comparisons between the suitability of those products to their individual or family requirements. Further studies would be useful to confirm this view.

What other sources of information might be available? [Buckner 1996] identifies computer user groups as useful sources of information, however, the home user is unlikely to join a user group in advance of purchasing either a PC or information products. We suggest that the home user is most likely to look to review articles to inform their judgement.

Relevance of Reviews

Reviews of information products are readily available to the majority of users who might consider purchasing information products for use in the home environment. Reviews appear in quality Sunday and daily papers; popular computing weekly and monthly magazines; lifestyle and other popular magazines; and, specialist magazines for librarians and educationalists. Most of these sources are available across the counter in newsagents, with a few being more normally obtained by subscription. Additionally reviews are appearing increasingly in electronic form on the World Wide Web (WWW).

Whilst reviews are available for the general public or home user, the literature on the content of and criteria to be used in reviews has tended to focus on reviews aimed at library and information science professionals, e.g. [Bosch & Hancock-Beaulieu 1995], [Zink 1991], [Harry & Oppenheim 1993a], and [Harry & Oppenheim 1993b]. However, [Clark 1993] agrees with [Gillham & Buckner 1996] that the characteristics of the home user of CD-ROM products, and arguably of their requirements from product reviews, are essentially different from those of the professional.

The reviews themselves tend to be limited in length to a few short paragraphs providing a brief overview of the information content, multimedia features and searching capabilities of the products. A certain style of review seems to have arisen (in the sources which *home users* are likely to read), reflecting the style of the products themselves, in which small easily digestible chunks of information are presented to the reader [Roberts 1996]. Does this matter? Do the reviews actually provide users with sufficient information to enable them to make informed decisions about which product to purchase? Do the reviews provide sufficient information on those criteria which the users identify as being important [Gillham & Buckner 1996]? Do the reviews provide sufficient information on those criteria which appeared to be important through observation of usage in practice? These are some of the questions which we attempted to address.

Aims of this Study

Consideration of the above has led us to determine three main areas as the focus of this study:

- to determine the nature of reviews and the criteria used by reviewers in assessing the products, including a comparison of information provided in different categories of print and electronic media.
- to compare the criteria from reviews with those which are important to home users including those which are identified by the user and those identified through observation.
- to devise a transferable methodology which can be used for evaluating information provision for other users of information CD-ROMs e.g. libraries, schools.

Methodology and Approach

Our first priority was to identify those sources of reviews which might be read by UK home users of CD-ROM products. Subsequently we were able to identify categories and sub-categories of media types. Two broad categories can be identified as print and electronic media. Some overlap may exist as some print media now also publish electronic forms of their publications e.g. national newspapers. Our categorisation is shown in [Tab 1].

The purpose of this categorisation was to enable us to a) ensure that we gathered appropriate data [Robson 1995], and, b) determine whether or not reviews offered in the different categories and sub-categories provided a different type of review to the reader and whether one type of review was more effective in terms of providing relevant information to the user. The electronic media category was mostly comprised of WWW sources but also included some newspaper sources from CD-ROM. We did not attempt to locate reviews posted in electronic news groups or other discussion lists.

Category and sub categories	Reason for selection
Print media	
Sunday and daily newspapers	Readily accessible by the widest audience.
Weekly and monthly computing magazines	Aimed at those actively seeking information about computers.
Lifestyle and other popular (non-computing magazines)	Aimed at those who have a lifestyle which may indicate they may have an interest in interactive multimedia products.
Specialist magazines (not normally aimed at home users)	Reviews aimed primarily at the information specialist but may also be seeking products for their own use.
Advertisements by CD-ROM publishers	Aimed at those seeking specific information about a particular product.
Electronic media	
Sunday and daily newspapers	Aimed at a wide spectrum of readers but not yet as widely read as print newspapers.
Reviews by public bodies	Reviews aimed at the specialist but accessible by all.
Ad hoc reviews	Reviews aimed at the general population but sometimes with a particular bias towards one group of readers.
Reviews by publishers	Reviews aimed at those seeking specific information about a particular product.

Table 1: Categories and Sources of Reviews

To limit variation in the data the sample selected was restricted to reviews of multimedia encyclopaedias and reference works. Sample size was limited to some extent by the resources and time available for the study; 31 reviews were included in total. Reviews were selected from the most recent issues and sources available. In all categories a range of publications and a range of products was used.

Once the sample selection had been completed the data was scanned using appropriate OCR software to digitise the data. Careful validation of the digitised data was important to ensure accuracy. A coding scheme was devised which would enable relevant components of the review to be coded against particular criteria. The review data was coded (using NUD.IST qualitative data analysis software [Q.S.R. NUD.IST 1997]) by the two researchers thus ensuring consistency of coding. Where ambiguity was a possibility definitions of coding criteria were developed.

For the entire document, reviews were coded according to media type (electronic or print); critical tone; product placing; main emphasis of the review; and whether the review had been written for a specific target audience. The text components (the minimum text component was one line) in each review were coded as either descriptive or evaluative. Components which were deemed to be evaluative were also coded according to whether the reviewer had adopted a positive, negative or neutral attitude. Sections of the documents comparing the product with other media types (CD-ROMs, Internet or print sources) were coded. At the detailed level we coded according to the categories discussed in previous studies by [Gillham et al.1995] and [Gillham & Buckner 1996]: textual information; multimedia; access; interactivity; aesthetics; interface; and system performance. Additional coding categories enabled us to look at other aspects such as quantity of information, authority with which it is written, depth of information, national focus and perceived purpose of the product.

Analysis and Discussion

Introduction

Analysis was carried out on the reviews which had been coded as described above. Three sets of figure are available for each of the codings made. These are:

- the percentage of documents that contain *some* text coded for a particular factor.
- the percentage of the text *about the factor* in those documents that *have some text* coded in the area of interest.
- the percentage of text *about the factor* in *all* the documents.

Nature of Reviews

A notable difference was found between the reviews appearing to be aimed at a general audience compared to those targeted at a more specialised reader. In the former category are reviews in newspapers, lifestyle and computing magazines and on non-specialist WWW sites. These reviews tended to be general in nature and at the detailed level were mostly concerned with the quantity and quality of the product often in comparison with competing CD-ROMs or previous versions. The latter included specifically educationally relevant WWW sites such as 'Superkids Educational Software Review' [Superkids 1996] and magazines such as CD-ROM Librarian. Reviews in this category were not generally any longer than the non-specialist ones but were more focused in their evaluation and less generally descriptive.

Of the reviews in the study 81% are essentially evaluative; only 19% (6/31 reviews) are purely descriptive and this includes the four electronic reviews from the publisher's WWW sites and one print based advertisement placed in a specialist computing journal. Whilst almost all documents (90%) have some purely descriptive parts most of the text (58%) in the reviews is taken up with analysis and evaluation. This often includes descriptions but at the same time is essentially evaluative e.g. about the timeliness of information; about the quantity of material in the product; about the effectiveness of search techniques.

Half of the reviews (52%) are about an upgrade to an existing or previously published product; 29% report on new products. Thus most of the reviews (81%) are topical which is to be expected given that the sources in which reviews appear are mostly what could be termed news oriented publications. It is noted that most reviews of upgrades seem to assume that the reader is familiar with the previous version.

Retrievals in 7 out of 31 documents (23%) stressed newness as the main feature of the review. Of these 7, 4 were from electronic newspapers (4/5 of the electronic newspapers) which stressed the timeliness of the information due to Internet links, for example:

"...there are Web links to even more in-depth (and timely) information: every month you get to download a Yearbook collection of some 50 news articles and features from the Encarta Web site. Figure about 600K per month ..." [CNET 1996]

However, as most of the electronic newspapers take their articles from articles which were initially written for the print medium we cannot necessarily assume that they are writing specifically for an audience which they know to be on-line.

Information was the key point of 23% of the reviews, whilst only one review was rated as having multimedia as the most important factor. Over half of the reviews (55%), had no specific emphasis and instead reported on a wide range of aspects. Less than one third (29%) of the reviews were considered to be targeted at a specific market. Most of these were from ad hoc WWW sites (3 of the 5 in this category) or from the specialist print journals (2 of the 3 in this category).

Stated Purpose of the Product

In 68% of the reviews a specific use for the product was mentioned. Research (including 'reference' use) is mentioned in 32% of all documents and 3.3% of the text units of these documents were about research, e.g.:

"All the essentials are of course here, tucked in alongside new features such as quotations, essays and bibliographies - extremely useful for research purposes." [PC Answers 1996]

Homework is mentioned in 16% of all documents and 2.4% of the text units of these documents were about homework. Fun is also mentioned in 16% of all documents and 2.7% of the text units of these documents were about fun. Education is discussed in about a third of reviews (35%), and 6.2% of the text units retrieved in these documents were about education. Commentary when the stated purpose related to educational aspects tended to be at a greater depth than commentary relating to other stated purposes, for example:

"The other part of the content aspect, the level of the material, was what I felt was a tad on the high side. I consider that the majority of the audience for this type of reference material is going to come from kids in elementary and middle schools, and the material seemed to be on more of an upperclass college level." [The Monitor 1995]

This excerpt is just a small part from a much lengthier section on the appropriateness of the level of the material to the perceived market.

Comparison with Criteria which are of Significance to Home Users

In our previous study [Gillham & Buckner 1996] home users ranked evaluation criteria in order of importance. The evaluation criteria used and the mean ranking figures are listed in [Tab. 2] along with some data on them from the reviews.

Evaluation Criteria	% of documents with this feature	% of text retrieved from all documents	Ranking by home users*
Searching	52.0	6.0	2.21
Textual content	65.0	5.5	3.23
Browsing	16.0	1.0	4.27
Multimedia	94.0	9.4	4.31
Aesthetics	42.0	1.5	4.31
Interactivity	35.0	4.9	4.85
System performance	26.0	4.2	4.92

(* mean ranking score from [Gillham & Buckner 1996])

Table 2: Comparison of Features Discussed in Reviews and by Home Users

In the 1996 study, home users ranked searching and text as the most significant features of an interactive product, however, when they were observed using the product they appeared to prefer looking at multimedia features such as video, pictures, animations and audio clips. As can be seen in [Tab. 2] the reviewers also rate multimedia features most highly in terms of the number of documents with some mention of multimedia (94%) and in terms of the amount of space allocated to them (9.4% of all text components). The highest ranked features (searching and textual content) from the previous study feature fairly highly in importance in the reviews. Both features are commented on by over 50% of the reviews (only multimedia is more prevalent) and they also make up a higher proportion of the text of reviews than the other features with the exception of multimedia. Browsing does not score highly in the reviews; this may be due to difficulties in its definition in coding, with review text on searching and browsing difficult to separate. Aesthetics is an area of interest; commented on in 42% of the review but only very briefly (1.5% of the text).

Towards a Transferable Methodology

The methodology which we have devised for evaluating multimedia information products has worked well for obtaining a general view of characteristics of reviews across a broad range of sources. Considerable differences in focus and depth were found between many of the reviews in the general sources compared with the more specialist ones. For example, it is noted above that commentaries on educational uses in specialist reviews were considerably more comprehensive than commentaries on application areas in the more general sources. It would be wise to separate these reviews in further analysis. Some further work is required to refine the criteria for classification of text elements; difficulties were encountered in maintaining consistency of coding because of the different styles and terminology of the reviews. To ensure validity during coding the definitions need to be tightened further.

Some further analysis of the current sample can be undertaken to investigate the value of multimedia information products to schools and for educational purposes but with a very small sample in these specialist categories the results would be somewhat suspect. While most of the results presented here have concentrated on the quantitative features of the coding system, the analysis software used allows the retention of the full text of the

BEST COPY AVAILABLE

reviews during analysis. This retains the richness of the data allowing more subtle inferences to be drawn from the texts than is possible with reference to the coding statistics alone. This helps greatly in our reflection on the coding used and its improvement.

Interactive Multimedia Software for a Course in Introductory Circuits

Brian P. Butz
Department of Electrical and Computer Engineering
Temple University
Philadelphia, PA USA
bpbutz@astro.ocis.temple.edu

Abstract The last decade has seen significant changes in education delivery technology. Computer use is now well integrated into electrical engineering education and courses in "Computer-aided........" are rare. The characteristics of the student population have also changed greatly during this time period. Students are generally more computer literate and much more accustomed to point-and-click interaction, on-line help documentation, and reading lengthy text files from a monitor than their predecessors were. Publishing companies are finding that fewer university students are purchasing required texts and much discussion on how effectively to integrate technology into the classroom is taking place. This paper discusses interactive multimedia software that is being developed for the introductory course sequence in electrical circuits. The philosophy behind the development is presented as well as a sampling an explanation of some of the modules.

Introduction

A continual challenge in teaching is meeting the students' academic needs and ensuring that they are active participants in their own education. Several studies have been made to determine students' learning styles [Montgomery 1995], [Felder and Silverman 1988] and indicate that students best learn actively and are more responsive to visual learning than to aural learning (lectures). Students are more attentive to visual lessons, seem to retain more of what they see over what they hear, and are more comfortable with visual learning. While texts are certainly visual, they tend to be static while computer software and computer networks have introduced students to dynamic visual material that may be modified by the user. As an example, many of the offerings in the venerable Schaum's Outline Series has an interactive version [Edminister 1995].

Interactive multimedia software can play a key and unique role in the educational process. It may be used as a stand-alone educational module that is intended to enable an interested individual to learn about a particular topic or subject [Sears and Watkins 1996]. It may be used as a supplement to classroom presentations [Doering 1996] and engineering laboratories [Mosterman et al 1996], or it may be used as a dynamic textbook [Harger 1996].

The interactive multimedia software described herein is under development and is a series of interactive modules that will reside on CD-ROMS. These modules could be used with appropriate textbooks on introductory circuits as a stand-alone study vehicle or as a strong asynchronous learning supplement to an on-campus course.

Overview

Many electrical engineering textbooks published today come with software that is bundled with the text. This software contains application or data files that may be used in conjunction with a course (for example, [Etter 1993], [Math Works 1992]). The software provided is usually an analysis package that may be used when performing tedious calculations, graphing results, and solving elementary design problems. Some included software contains examples that a student may view or even change the values of the parameters to see how these variations affect the solution. For example, the Schaum's interactive outline on electric circuits [Edminister 1995] comes with Mathcad embedded within it so that the student may modify illustrative problems and use the Mathcad scratchpad to perform calculations.

The software being developed and presented here is different from these types of packages. It deals with concepts, applications, and visual tours that go well beyond the standard analysis package often accompanying textbooks. This interactive multimedia is a series of modules that together form an electric circuits tutor. Each module is associated with a basic topic in introductory circuit analysis. There are three basic module types: the *study* module, the *applications* module, and the *examination* module.

The *study* module consists of an interactive exposition of the material necessary to understand the topic being studied. For example, the module on circuits, charge, and current flow shows the student what a circuit is , what charge is , and how the movement of charge is current, and finally the concept of current direction and reference current. Some very basic concepts such as the passive current convention, current division, voltage division, and the notion of elements in series or parallel are especially difficult for some beginning students to grasp. Animations should make these and other concepts much easier to understand. Basically, the study module is an interactive lecture somewhat similar to a classroom experience in which there is information exchanged in both directions between a student and an instructor.

A second kind of module is the *applications* module. This module consists of demonstrations, design examples, and tours of various aspects of electrical engineering. Movies, audio clips, and animations will be generously used in these modules. Examples of the kind of exercises that could be seen in these modules are simulations of very basic laboratory experiments, movies on power production that show briefly the working of an electric power plant, and rather rigorous problem solving sessions. The purpose of the applications module is to show the student the practical use of the topic studied and an interactive experience based upon the knowledge acquired in the study module.

The third module is the *examination* module. This module tests the student on the material covered by the two other modules and grades the test automatically. Questions are randomly generated so that no two students' examination would be the same. It is not intended that this modular examination replace either traditional in-class or take home examinations. The instructor's role in testing is an important one because he/she can evaluate what a student does and does not understand. Moreover the instructor can ascertain why students do not understand certain topics from carefully crafted examinations. Instructor grading provides invaluable feedback and allows the instructor to stress certain topics, change presentation methods, and, if necessary, redo certain parts of a course. However, the examination module provides the student with fast, reliable feedback *before* the traditional examination and may catch learning deficiencies before they become ingrained. Moreover, the examination module may be used to grade the work and present an accurate evaluation of a self-study student.

Today there are many software tools for producing interactive multimedia applications. These tools are used to create an environment that simplifies the authoring process and act as an assembly point where photos, movies, animations, audio clips and original material may be more easily integrated. The modules described here have been developed using Macromedia's Authorware [Macromedia 1995] as the authoring tool. Authorware was chosen for four reasons: 1) It has a relatively short learning curve for its basic use. 2) The programming consists of placing icons on a flowline which acts as a script and determines the sequence in which Authorware executes them. The resulting flow diagram is easy to read and different individuals can work on the same piece or integrate pieces without much difficulty. 3) Authorware is a cross platform tool and can run on both PC's and Apple computers. 4) The modules can be packaged as executables so that a user need not have Authorware to run the modules.

The Modules

The electric circuit tutor interactive multimedia software under development will contain a series of study, applications and examination modules.

The Study Module

The study modules cover specific topics that are contained in nearly every elementary circuits textbook. Examples include: Circuits, charge and current flow; Electric potential and voltage; Resistivity, resistance, and Ohm's Law. The study modules cover the material by emphasizing student interaction and decision making. If a student has read the textbook, the study module is designed to provide an interesting and thought provoking way both to review the material and to get another perspective on the material other than that of the author of the textbook. This module is designed to supplement a textbook--not replace it. If the student has not read the textbook, he or she will be able to learn from the study module , but it will become clear that the text is a necessary partner in the learning process.

A flowline for a typical study module is shown in Figure 1. The introduction announces (video and audio) the title of the module and gives any special instructions. The objectives map (expanded and shown as the "objectives" window in Figure 1) presents the student with the objectives of this module. When there are multiple objectives (the usual case) the objectives are presented one after another on the same screen. The rest of the flowline varies with each module. The "Ques. 1 Curr Dir" window in Figure 1 shows the flowline of a simple animation. First, positive charges are moved across the screen from left to right (see Figure 2), then, the student is asked to show the direction of current flow. The exercise is repeated for negative charges. The frame entitled "Hot Words" shown near the bottom of window "mod1s.a3w" shown in Figure 1 is where the results of clicking hypertext (hot words) are stored.

Figure 1. Flowline of a Typical Study Module

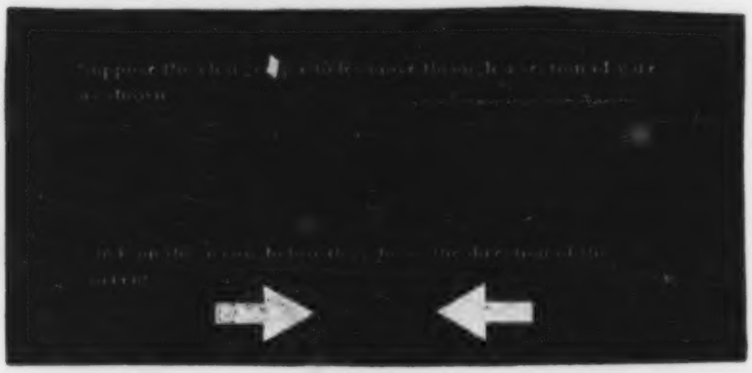

Figure 2 Sample Animation on Current Flow

Within the study module there are many explanations, animations and other ways students may interact with the material. Figure 3 shows a screen that demonstrates the passive current convention. The format of the screen is typical of many of the modules. On the left side of the screen shown in Figure 3 is an explanation of what is happening or what will happen. The right side of the screen is the animation or demonstration. The arrow moves from top to bottom. As the arrow representing current moves "through" the element, a positive and negative sign, each highlighted by a circle, are placed at terminals A and B, respectively. The thin arrows and the text from which they

BEST COPY AVAILABLE

emanate are then added. Finally the explanation at the bottom of the right hand side of the screen is added. When finished, the student clicks the continue button and proceeds onward.

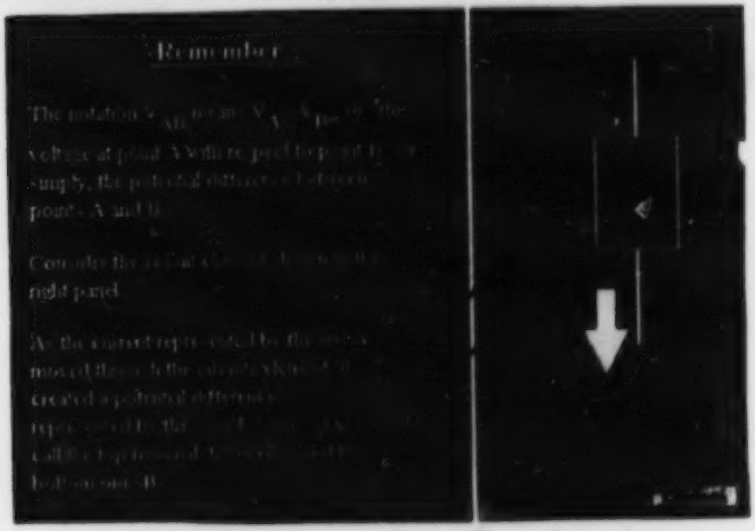

Figure 3 Demonstration of Passive Current Convention

Another way of interacting is through multiple choice buttons. In Figure 4 is a question about potential energy posed to the student after a discussion about it. The student presses the button representing an answer and then is told if the answer is correct or incorrect. If incorrect, an explanation as to why is given. Other interaction techniques include building the circuit that satisfies certain specified criteria using a point and drag technique, selecting objects that represent correct elements, circuits, measurements, etc., and questions with time limits. The philosophy of the study module is that the set up material, the lecture if you will, must be very brief. Demonstrations and animations are very important and show the student how to perform a certain task or explain how something works. Audio is used sparingly in the study modules. Students are directed to their instructor if it is detected that they are having problems with a specific concept.

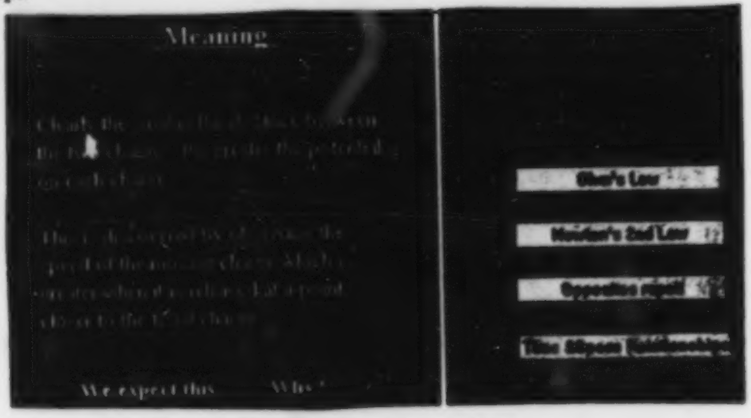

Figure 4 A Question on Potential Energy

The Examination Module

One of the strongpoints of the Authorware authoring software is its ability to judge, track, and record a student's performance. Judging means determining whether the student's response is correct or incorrect. Tracking means collecting and storing data about how a student reacted during the examination. For example, how many times

BEST COPY AVAILABLE

the student tried to get the right answer and how long was spent on each problem. Recording means saving all or selected portions of the information that Authorware obtains in a file so that it may be used later [Macromedia 1995].

Each examination covers the material contained in one or more study modules. The examination modules are rather formal examinations similar to in-class tests. The student would use a calculator or could use problem solving software such as MATLAB through a window accessible from Authorware. The other software may be made accessible to the Authorware user through Microsoft's dynamic data exchange protocol as long as the software resides on the same system as the Authorware executable. Although the examination module is the formal testing module the study modules are also testing modules in that they require constant interaction and decision making by students.

The flowline of a typical examination module is shown in Figure 5. As shown the module begins with an introduction that identifies the module and provides detailed instructions on how to proceed. The student enters his or her name and a password. This enables the student's responses and other relevant information to be recorded in a file. It also enables the student to quit the exam at any time and to resume where he or she stopped. The additional data generated by the student will be added to the student's examination file. The test consists of questions grouped by subject area (e.g. current and voltage dividers) for easier report filing but they need not be. For example, Group 1 consists of six questions on resistivity, power and energy. The student is given three questions generated randomly from this group to answer. Consequently as the question base is made larger the number of possible different tests increases dramatically. Most of the questions require the student to respond with a numerical solution of with an equation from which the student may be calculated. The report mentioned in the flowline of Figure 5 is actually several reports to the student. Figure 6 shows the performance report for a student after being tested on Group 3 which covered resistors in series. Since a student is able to submit, then change, a response to a question there may be more responses than questions asked. The student is told how many answers are correct and incorrect and how much time was spent on the group. The instructor gets much more detailed information as shown in Figure 7. Besides the information that the student gets the instructor gets a listing of every answer and response the student makes on the test. This will help the instructor locate areas of misunderstanding for each student.

BEST COPY AVAILABLE

The examination modules are really self-examination modules in that they are written to help students gauge their progress and help the instructor pinpoint areas of difficulty. They are not designed to replace an instructor's normal testing protocol.

The Applications Module

Applications modules allow descriptive material, experiments, and expository material not easily available to students to be brought into the course. These modules contain simulated basic experiments such as measuring voltage and current, constructing circuits to demonstrate current and voltage division, etc. Also there will be video clips that allow students to "visit" industrial locations and will give the students a better feel for the relevance of the material within the engineering profession. Finally, some of the applications modules deal with the pioneers of electrical engineering and their work and will allow students to get a better feel for the historical development of electrical engineering.

Final Comments

Interactive multimedia holds promise for enhancing collaborative learning. As authoring tools become more sophisticated interactive multimedia could play a key role in the total educational experience. Especially intriguing is the artificial intelligence aspects as the authoring tool environment that may eventually allow instructors determine what faulty logic process or incorrect understanding of theories prevent students from learning correct techniques and methodologies.

At present there is a downside to developing interactive multimedia modules. There is a learning curve for the authoring software. Moreover the authoring software is but one in a series of packages that are used. Various packages are needed for recording and editing audio clips, scanning and editing photographs, developing and editing movies, creating animations, and burning CD ROMS. The usefulness of the software is impacted by the financial stability and the support commitment of the vendor offering the software. Changes in operating systems and radical upgrades can cause difficulties in maintaining an efficient development environment. Very important is the amount of time it takes to put together modules (one rule of thumb is that it takes 100 minutes of effort for every minute of completed work). Mastery of the subject material is but one aspect of the total effort. Mastery of all the software plus an ability to marry the subject matter and its presentation in a captivating and innovative way is no small task. Even with these difficulties, interactive multimedia offers a new and exciting environment for learning.

Abstract: In textbooks the different topics are introduced in an order which is (supposedly) the best way for learning the subject at hand. Once the student masters the subject, most textbooks are not well suited for use as reference material, because related topics are not located near each other. This paper presents a framework for self-modifying hyperdocuments. A textbook, delivered as on-line hypertext, transforms itself into a reference book during the learning process. This is accomplished by modifying the link structure and the node contents each time a hypertext link is followed. This framework is illustrated by means of the courseware for an on-line course on "Hypermedia structures and systems", developed at the Eindhoven University of Technology, and currently offered at six different universities in the Netherlands and Belgium, by means of World Wide Web technology.

1. Introduction

Hypertext is being used more and more often in distance education, as a replacement for paper course texts. A textbook usually suggests only one (linear) reading order. The student can of course elect to read the pages in a different order, but it will always be obvious to her that she is deviating from the intended reading order, and in many cases such alternative order does not make sense. A hypertext offers many (supposedly) intended different reading orders. Every page (or node) contains links to a number of different pages which can be read next. Despite this flexibility, the link structure in a (hyper)textbook cannot offer complete navigational freedom because concepts must be introduced or defined before being used, and storylines must be preserved. This implies that detailed or advanced pages must only be accessible after reading introductory pages. Such a link structure makes a hypertext version of a textbook unsuitable as a reference book, because the advanced information, which is used most in such a book, is not directly accessible from the starting page(s) of the course text.

The most important factor rendering course texts unusable as reference material is the inability to change the terminology or wording depending on the student's progress through the course, or to change the link structure during the learning process, to enable links to advanced pages from the starting page when the student is ready to read and understand them. As an example, in a course text on the subject of hypertext, the word *page* can be used to indicate what is normally called a *node* (in hypertext terminology), until the student has read an explanation of the concept of *nodes*. Almost everywhere the word *node* is needed in the course text the word *page* can be substituted automatically, until the definition of *node* is read. Such minor variations in textual content are unobtrusive. The student will probably still recognize the text when visiting it again, so she will not be tempted to read it all again as if the node were completely new. Larger variations in a text can of course also be introduced, but may confuse the reader because a page she thought she read before would suddenly look completely different.

Variations in the link structure are not only needed for modifying the access path to advanced reading material. In a textbook it is common to first define a concept or term, and then move on to the applications of that concept.

---

[1] Paul De Bra is also affiliated to the University of Antwerp and the "Centrum voor Wiskunde en Informatica" in Amsterdam.

In reference books, the opposite order is sometimes also used: throughout the text some concepts or terms are used, which the user may or may not know; links (or references) to the definition of these concepts or terms provide access to these definitions, so the reader who isn't aware of an exact definition can easily get to it. Such cross-references are also used in textbooks, but in most cases for backward references (pointing to information to review if needed), and seldom for forward references (pointing to previously unread information). Hence, the modifications to the link structure that are needed to transform a textbook into a reference book are more intricate than simple "unveiling" of links when the reader is ready to follow them.

This paper describes research and experimentation with dynamic hypertext structure and content, in order to guide the student through the learning process, thereby slowly transforming the course text from a textbook into a reference book. Prototype software has been written to enable teachers to create and deliver such dynamic course texts through World Wide Web. A successful course on "Hypermedia structures and systems", organized by the Eindhoven University of Technology, and offered (through the Web) to students at six different universities in The Netherlands and Belgium, is now being used as a test case for evaluating the use of this dynamic hypertext courseware. This course was chosen because hypertext is not only the medium through which the course is taught, but is also the subject matter of the course.

This paper is organized as follows: Section 2 gives a brief review of previous research on adaptive hypermedia. Section 3 describes the possibilities and dangers of using dynamic link structures, and shows how they are used in the hypermedia course. Section 4 shows how the addition of dynamic node contents can improve usability of hypertext courseware even more, but also how it can confuse readers if used carelessly.

2. Quick Review of Adaptive Hypermedia Research

Since the early seventies computer-assisted instruction (or computer-aided instruction, or CAI for short) researchers have been trying to develop adaptive systems by mimicking human-to-human interaction [Wenger 1987] [Self 1988]. However, the first attempts at putting documentation on-line closely followed the existing book model. Hypertext links were only being used for linking from a table of content or an index to the appropriate pages, and for explicit ("see also") cross references. This did not remove the essentially linear style of the presentation, thereby making it difficult to convey non-linearly structured information.

A primary concern when using hypertext for the creation of a course text is the structure to be given to the knowledge it conveys so that students can easily and naturally find the most appropriate information depending on their needs [Bareiss et al. 1993]. To make information presentation in a hypermedia environment effective and its management efficient, it is necessary that text, graphics, and images are properly coordinated [Hekmatpour 1995]. Some researchers, e.g. [Feiner et al. 1991], [Maybury 1991] have investigated the automatic generation of coordinated multimedia; [Carver et al. 1996] for instance have proposed (and implemented) a system for generating personalized hypermedia course presentations depending on the student's learning style, rather than based on the student's (fore)knowledge. From the learning style they generate a selection of prefered media types, but then go on to generate a linear presentation of multimedia information objects. [Merlet 1993] has focused on how to control and manage the diverse elements that concur in the composition of a multimedia document. What has emerged from all these (and other) studies, and what they all share, is the fact that they have shown and proved the inefficiency of the classical book model for on-line systems. This does not yet address the specific requirements and limitations of the on-line presentation of information through hypermedia systems.

Reading paper documents demands that the reader adapts to the level at which information is presented. Often too few details are provided to avoid the need to consult other sources of information. (A bibliography at the end of the book refers the reader to more information.) But also, often too many details, background or other information are given which the reader wishes to skip. When a book is presented on-line it becomes much more difficult to skip unwanted parts than with a paper document. Turning pages and very quickly skimming the text is something most, if not all, people can still do more easily with a (paper) book than with an on-line document. (We can, for instance, often find a certain illustration in a 200 page book in under 2 seconds by flipping the pages very rapidly, but we cannot yet do this with an on-line system.) In a hypermedia system it is possible to adapt to the reader by applying technology from intelligent tutoring systems or artificial intelligence, but even the simple technique of putting introductory information or summaries in separate nodes that provide links to nodes with detailed information can significantly improve the usability of a hyperdocument for a varied audience.

Most previous studies on adaptive systems have only focused on dynamically assembling information and presenting it according to the user's class and/or knowledge state without including the user's learning procedure in identifying which information to present to students. [Carver et al. 1996] are an exception to this, since they do apply learning styles to select media types, but then use them to generate a linear multimedia presentation, not really a hypermedia presentation. In the framework we propose we adapt the selection of links and the content of nodes without switching between media types. In fact, in the hypermedia course at the Eindhoven University of Technology almost all information is offered as text only. Furthermore, we propose not to assemble information nodes, but to limit textual modifications to otherwise static nodes. Slight modifications are enough to avoid the use of technical terms or concepts for which the user has not yet read the definition.

3. Using Dynamic Link Structures

The organization given to on-line documentation mostly depends on the kind of information that has to be delivered. However, whatever the structure may be, the underlying purpose in outlining the subject matter is to make it as simple and as useful as possible [Rojas-Fernandez 1991]. An unstructured information space topology can indeed give rise to problems similar to the GoTo statements in computer programming [Tomek et al. 1993]: difficulties on the side of the user in understanding the application domain and a consequent navigation breakdown due to uncontrolled linking.

Graph-theoretical methods have been used [Botafogo et al. 1992], [Begoray 1990], [DeYoung 1990] for analyzing link structures. These methods identify link structures that are unusable no matter what the content of the nodes is and regardless of the visual aids that may be provided to help the user in understanding this structure. To quote DeYoung [DeYoung 1990]:

> "(...) if a hypertext is a densely connected unstructured graph, no presentation of the mess is going to clean it up or make it conceptually easier to understand."

However, while these methods are able to find link structures which are likely to be unusable, they cannot guarantee that link structures having all suggested values for different metrics will actually belong to highly usable hyperdocuments. Empirical findings have demonstrated that links are often introduced without a deep consideration of their actual use and usefulness [Campagnoni et al. 1989]. Because of the lack of a clear methodology for linking as well as of a common understanding of what the notion of link eventually means, users often happen to be unable to understand why some piece of information is at the end of a certain link and they may also fail to understand why they are sometimes unable to find what they are looking for [Landow 1987]. So, linking one piece of information to another can not only fail to provide the expected benefits, but, in some cases, it even frustrates users. Since the mere presence of links in a hyperdocument seems to suggest that the relationship between the interconnected materials is a significant one, it becomes very difficult for users to ignore them.

Instead of searching for the "ideal" link structure for a hyperdocument, we opt for a system that adapts the link structure during the browsing process. A static link structure, possibly displayed graphically to provide a better overview, uses a "spatial metaphor" for guiding the user. Our approach, with links that are created and removed at different points during the browsing process, uses in some way a "temporal metaphor" [Calvi 1996]. However, because as soon as temporal relationships are mentioned in a hypermedia context this concept is often interpreted as involving real-time aspects, we will not use the term "temporal" to describe our approach, but rather use the terms "dynamic" or "adaptive".

A common problem with static hypertext is the abundance of links, many of which may not be appropriate at all times. As part of the course 2L690, "Hypermedia structures and systems", at the Eindhoven University of Technology, students have to convert a (linear) review of hypermedia research (by V. Balasubramanian from Rutgers University) into a hyperdocument by splitting the document into reasonably sized nodes and by adding links. Some pages offer an explanation of concepts that are used throughout the text. A typical example is the page describing what *nodes and links* are. Both the course text and the hypertext review used for the assignment contain a page describing what *nodes and links* are. In the (dynamic) course text the student is carefully guided to the definition page early in the reading process. In the hypertext review used for the assignment this is difficult to achieve because the table of contents invites the reader to go off in any desired direction. Almost all students create a large number of links from pages throughout the review to the *nodes and links* page (and to some other descriptive pages). The navigational possibilities of each student's version of the hypertext review are so overwhelming that it is difficult to predict where the reader will meet the concept of *nodes and links* first. Consequently the students create links to the *nodes and links* page from every possible source. Because in this assignment work the students can only create a static link structure, their only solution would be to select interesting places for linking to the *nodes and links* page very carefully. The students have neither the time nor the skill to perform this task.

The software for the hypermedia course keeps track of all nodes read by each individual student. With each node three "knowledge identifications" can be associated:

- **Required knowledge** is knowledge that is needed in order to view this node. The system will automatically hide (conditional) links to nodes for which the user has not yet acquired this knowledge.
- **Forbidden knowledge** is knowledge that makes viewing this node uninteresting. The system will automatically hide (conditional) links to nodes for which the user has acquired this knowledge.
- **Generated knowledge** is knowledge the user gains after reading this node. (By "after" we mean that a node which generates its own forbidden knowledge can be viewed once, because the forbidden knowledge is only gained after visiting the node.)

Whether certain links appear or not depends on the combined knowledge id's a student has acquired. But regardless of the student's knowledge, there are also **unconditional links** which are always shown.

Using knowledge id's we can make links accessible when the reader is ready for them, and make them inaccessible again after the reader has no need for them anymore. The link structure of the course text changes each time the student follows a link. This technique is used in the courseware for the hypermedia course in the following way:

1. When the student first visits the course, the starting page gives some kind of table of contents, but provides no other links than one to a node containing instructions about the use of this courseware.
2. When the student returns from the instructions page, the first three "chapters" of the course text become accessible. These chapters are an introduction, a set of definitions, and a historic overview of hypermedia research and development. The student may follow different paths through these chapters, and depending on the path taken, the link structure within these chapters may also differ.
3. After reading some of the nodes of these chapters, and completing a small (multiple-choice) test at the end of each chapter, links to the more advance chapters appear in the table of contents.
4. While reading, some links will disappear. Links to definitions of terms will disappear after reading these definitions. Links to nodes containing unimportant background information will also disappear after looking at that information (in the hypermedia course there are nodes that briefly describe the IBM PC, the Macintosh, etc. which we do not expect the student to wish to read multiple times).
5. After reading (some of each of) the advanced chapters, a link to the final assignment appears in the table of contents.

Figure 1 gives an impression of what the table of contents page looks like, when only the first three chapters are available.

Hypermedia structures and systems

Welcome to course 2L690 at the Eindhoven University of Technology.
If you are just beginning to browse through this course, you should first read the instructions. . .
This course contains the following (not necessarily disjoint) parts:

- Introduction (it is advised to read this before the other items)
- Definition of hypertext and hypermedia
- The history of hypertext and hypermedia
- The architecture of hypertext systems
- Navigation (and browsing semantics) in hypertext
- . . .

Figure 1: Possible table of contents of the hypermedia course.

From the example of the hypermedia courseware it is clear that a dynamic link structure can be used to eliminate confusion that could be caused by providing links to information the student is not yet ready for, or that the student has already read and may not wish to find other links to. However, seeing a different selection of outgoing links each time a node is visited can also be confusing. Therefore, the pages with a varying link structure must be limited and well chosen. The table of contents is an excellent candidate for a node with a varying link structure. Through the links in this node large parts of the course text can be enabled at once. In the hypermedia course, most other use of dynamic link structure is in the elimination of links to definition nodes and to unimportant background information.

From figure 1 we may observe that apart from the presence of links, the presentation of the path leading to different chapters is identical. No reason for the absence of links to the advanced chapters is given. Similarly, pointers to the definition of *nodes and links* are given in the introduction, while the use of these terms could be easily circumvented, thereby eliminating the need for guiding the reader to that definition. A solution for these problems is presented in the next section on dynamic content.

4. Dynamic Content, or How to say something in Other Words

A student at the Eindhoven University of Technology developed a first hypertext courseware on environmental law back in 1990. In order to circumvent the need for learning lots of definitions and terms right at the start of the course two versions of each node were produced: one using common English vocabulary and one using the proper technical terms. Depending on the knowledge of the student (which was measured in a way somewhat similar to our current approach), the introductory or the advanced version of a node was presented. As a result of offering different versions of the content of a node the link structure could also vary, because some links that were present in one version of a node might not be present in the other version.

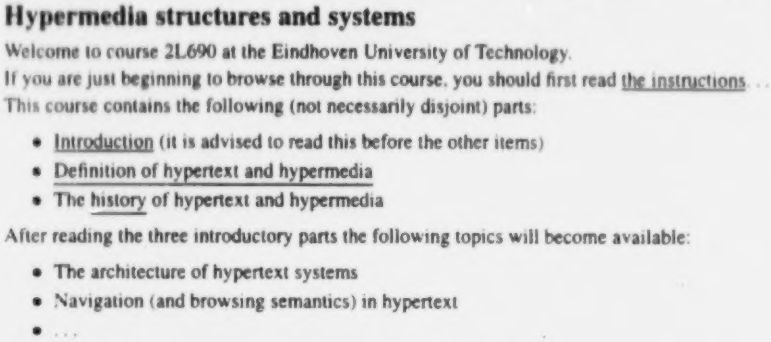
Having two (or more) completely different versions of a node can be confusing:

- After reading the introductory version of a node a student may continue browsing, thereby gaining the necessary knowledge, and then revisit the node without knowing so and reading the advanced version without realizing it is actually the same as the introductory version, up to some rewording.
- Because students may not revisit a node after reading the introductory version, the author must make sure that that introductory version contains the same information as the advanced version. Authors may be tempted to leave out important parts because they are difficult to describe without using technical terms.
- Different parts of a node may depend on different definitions or terms. One would like to have more than two versions of the entire node. Maybe two versions of every paragraph or sentence would satisfy this need. However, nodes which contain some paragraphs using concise technical vocabulary, and other paragraphs with plain English vocabulary may be very awkward to read.

In the software for the hypermedia course, the Unix C preprocessor is used to select between arbitrary pieces of text (using #if constructs). Although this offers the possibility for large modifications, we use dynamic content only for small variations in content:

- In the table of content (and other places), additional text is added to explain why certain chapters are still unavailable.
- In the text, some technical terms, like *node* and *link* are carefully replaced by the non-technical terms *page* and *reference* or *cross-reference*.

Figure 2 shows the table of contents for the hypermedia course, after applying dynamic content modification.



Hypermedia structures and systems

Welcome to course 2L690 at the Eindhoven University of Technology.

If you are just beginning to browse through this course, you should first read the instructions. . .

This course contains the following (not necessarily disjoint) parts:

- Introduction (it is advised to read this before the other items)
- Definition of hypertext and hypermedia
- The history of hypertext and hypermedia

After reading the three introductory parts the following topics will become available:

- The architecture of hypertext systems
- Navigation (and browsing semantics) in hypertext
- . . .

Figure 2: Table of contents with dynamic content modification.

5. Conclusions

Using hypertext for course texts is non-trivial because the navigational freedom, typically associated with hypertext, may conflict with the need to study concepts and definitions before moving on to applications or advanced topics. Dynamic link structures and content can be used to guide the student throughout the learning process, while preserving as much nagivational freedom as desired. Hypertext textbooks can be transformed into reference books by gradually changing the structure during the browsing process.

However, the use of a technical framework for supporting dynamic link structures and dynamic content does not guarantee a usable result. Dynamic link structures must be used with care because unexpected changes in the link structure may confuse the student, and excessive content changes may cause students to read the same (but rephrased) information several times, not realizing that, or wondering whether two such versions represent the same information or not.

In the course "Hypermedia structures and systems", taught (only) through World Wide Web at the Eindhoven University of Technology (and taken by students at six universities) we are using dynamic link structures and dynamic content sparingly, in order to benefit from this framework, without causing more confusion with the students. All browsing actions of all students are currently being logged for later evaluation and for comparison with previous logs of students who have used a version that had no dynamic link structure and no dynamic content.

BROCA: A Computerized Environment for Mediating Scientific Reasoning through Writing

Patricia A. Carlson
Rose-Hulman Institute of Technology
Terre Haute, Indiana, USA
Email: Patricia.Carlson@Rose-Hulman.Edu

Abstract: This paper describes a computerized learning environment for teaching the conceptual patterns of scientific reasoning. BROCA (Basic Research, Observations, Critical Analysis) is theory-driven, combining two very powerful conceptual models of thinking. The first – drawn from cognitive psychology and information theory – focuses on the mental manipulations by which data becomes information and information becomes knowledge. The second theoretical construct comes from rhetoric and describes the intellectual activities carried out in prewriting, drafting, and revision by an expert writing. As an interactive "cognitive tool," BROCA provides scaffolding (through visual algorithms and adaptive prompting) to help a fledgling thinker practice the robust patterns of scientific reasoning.

1 Introduction

The written word is crucial to science for at least two compelling reasons. First, the texts of science -- publications that report findings -- are the life blood of progress for a community of researchers. Framing a question of interest, designing an experiment, collecting data and observations, analyzing the raw findings, and interpreting results in light of theory -- all these demanding tasks are the *process* of science, but the written word provides the vehicle for dissemination of the *product*.

Second, writing is important to science because the act of placing ideas into language mediates higher-order intellectual activities that are foundational to scientific thinking [Kuhn, Amsel, & O'Loughlin, 1988]. Though other symbol systems play a major role in scientific reasoning, language fosters mental manipulations such as synthesis, analysis, classification, inferencing, definition, hierarchical order, comparison/contrast, elaboration/extension. Some of the most respected of twentieth-century educational theorists have endorsed this notion of writing as a vehicle for learning and for understanding. Vygotsky [Vygotsky, 1962], Luria [Luria & Yudovich, 1971], and Bruner [Bruner, 1971], to name only a few, have pointed out that higher cognitive functions seem to develop most fully only with the support of verbal language -- particularly, of written language.

In broad terms, the process of scientific inquiry mirrors the writing process. Both the scientist and the writer go through an initial gathering and sorting out of ideas, from which tenuous though testable explanatory notions are made (hypotheses for the scientist and thesis statements for the writer). After considerable trials, sound relationships between entities are found (experimentation for the scientist and drafting for the writer) and a supportable belief structure emerges. Continued scrutiny (replication in science and revision in writing) results in knowledge -- an artifact that can take its place in the body of received opinion. Because of this similarity of intellectual activities, writing can be used as an analog for scientific thinking.

This paper describes a multimedia, interactive learning environment that weds forms of scientific inquiry to forms of scientific discourse. BROCA (Basic Research, Observation, and Critical Analysis) is an end-to-end knowledge development environment that mediates the intellectual activities implicit in scientific thinking. Our claims are that BROCA – when integrated into an appropriate curriculum – will:

- Increase competence, creativity, and confidence in formal reasoning.
- Promote and sustain interest in scientific investigation.
- Engage the user and transfer powerful strategies for problem-solving.
- Bridge the gap between process (thinking) and product (writing).
- Improve quality of writing by improving quality of thinking.

BROCA aids learners in two specific categories of intellectual activities. First, the software aids the user in harvesting existing information artifacts (e.g., websites, electronic databases, professional literature, as well as hands-on experimentation). Second, BROCA guides the student in the processing and interpreting of these sources to find patterns of meaning that answer a specific research question. BROCA does not contain any "canned lesson." Its content consists of a set of "inquiry tools" and a supplemental curriculum that provides five "authentic" content domains from which the learner formulates a problem and conducts an investigation.

2 Curriculum and Instructional Design

BROCA is the foundation for a multi-disciplinary course, "Writing as Reasoning in Science and Engineering." However, the software is not intended to be "stand-alone." It is a teaching resource to be used in conjunction with a problem-oriented course that presents writing (and other variations on "image-making" and visualization) as a vehicle for scientific inquiry and critical thinking. Additionally, when delivered as an "empty engine," the BROCA software can also be adapted to other, more technical courses, provided the instructor shares the basic premise that writing is central to the deep-learning of scientific concepts and content.

2.1 Course Content

For "Writing as Reasoning in Science and Engineering," five content domains were selected in order to make use of the unparalleled scientific resources garnered by U. S. government agencies. Current U.S. policy has mandated that all Federal agencies make their wealth of materials, facilities, and expertise available to educators and students. The course sequentially presents students (working in teams of three or four) with opportunities to conduct investigative studies within five "authentic" domains.

- *Non-terrestrial Ecosystems:* Research into Advanced Life Support for Lunar and Mars habitation is being carried out at several NASA Centers (e.g., Ames, Kennedy, and Johnson).

- *Astronomy and Instrumentation::* Drawing from NASA's archives of data and images, this unit asks the learner to work with research problems dealing with stars and stellar evolution.

- *Applications of Remote Sensing Data:* This suite of problems is taken from scientific resources on near-earth imaging, drawing from NASA, DOE, and the National Center for Global Environmental Change (NIGEC) databases.

- *Designing and Engineering for Zero-Gravity:* This module presents materials from NASA's extensive experience in "mechanics" as applied to a zero-gravity environment.

- *Science and Public Policy:* The last module focuses on science policy and decision analysis by examining rich case studies dealing with funding.

The "questions" students formulate and then investigate are on the order of a "thought experiment." In other words, they are scientific in nature, but they are open-ended and their solution(s) can be derived (or more appropriately "imagined," then reified through research, development, and verification) through methods of thinking more speculative and imaginative than classical scientific investigation might foster.

2.2 Instructional Design and Cognitive Theory

A thought experiment is intended to liberate the scientific mind from the rigors of formalism and to allow for a new way of thinking about bold (wild versus tame), ill-defined problems. We have designed the BROCA exercises to use both qualitative and quantitative methods, to engender both analytical and holistic thinking, and to incorporate creativity, imagination, synthesis, informed guessing, and even serendipity into the more routine definition of the problem-solving process.

The actual BROCA software contains mediated workspaces and suites of inquiry tools (cognition enhancers) to teach the strategies of investigating, thinking, and writing. However, the resource materials for all the content units are distributed across a range of information forms (artifacts) and sources. [Fig. 1] depicts the distributed nature of resources and the centralized tools for inquiry in the BROCA "learning environment." As currently designed, students construct their own research agenda, but are pointed to several rich sources for initial investigation.

Traditional Library Resources
Traditional Audio-Visual Resource
Internet/WWW
Hands-on Experimentation

Figure 1: BROCA's Centralized Inquiry Tools Act as an Interface for Decentralized Information Resources

Each "thought experiment" draws from a combination of disciplines: geology, biology, chemistry, physics, meteorology, and ecology, as well as economics, politics, and social and ethical considerations. However, the problem does not depend upon a thorough understanding of the "theories" or "method" or body of "facts" of any one discipline. Rather, BROCA works at a higher level to help the learner generalize both cognitive and meta-cognitive strategies for rational problem-solving. Using the online inquiry tools built into BROCA, the learner will be able to:

- develop strategies for information gathering,
- recognize patterns and relationships,
- evaluate strengths and weaknesses of data,
- predict outcomes using extrapolation or interpolation,
- and design and conduct focused investigations after the formulation of problem statements.

3 Developing Software to Mediate Scientific Reasoning

We base the design of BROCA on two explanatory models: one from information science and one from cognitive science's finding on discourse strategies. We do not intend our resultant hybrid model to be reductive or prescriptive. Rather, we see this "cognitive tool" [Salomon, 1993], [Salomon, 1988], [Salomon, Perkins, & Globerson, 1991] as an enabling prosthetic to help scientists-in-training recognize and take control of demanding intellectual processes.

Our first model comes from the general premise that there is a qualitative difference between *data*, *information*, and *knowledge*. Data are discrete entities, such as facts. While a body of *data* assembled for a specific purpose undoubtedly has relationships among the elements, these patterns of meaning must be extracted through an examination of the set and a filtering out of extraneous pieces. The systematic processing of data produces *information*, or statements about the associations in the data. Information is a codification and a clarification of the connections in data that produces more compact and easily remembered interpretative statements. A synthesis of information builds belief structures more comprehensive and more resilient than those contained in information.

Thus, *knowledge* is more powerful than information in that it has predictive or explanatory value. In other words, knowledge structures become both the product and the continuing impetus for such intellectual activities as exercising judgment and making rational decisions. These differences -- and more importantly, the transformations that take place when moving up the ladder of abstraction -- are the foundations of human memory and thinking. Moreover, this hierarchical model of knowledge evolution is central to many of the emerging applied fields coming out of the cognitive sciences.

Our second model comes from the cognitive science research into the importance of strategy acquisition for thinking and writing. Generalized models of good thinking include an array of techniques (strategies) for accomplishing goals, knowledge about when and how these techniques should be used (metacognition), and an extensive, task-specific knowledge base that is used in conjunction with the strategic and metacognitive processes [McCormick, Miller, & Pressley, 1989]. Realization that good thinkers have a repertoire of problem-solving behaviors for various types of tasks launched a new pedagogy for strategy acquisition.

[Fig. 2] illustrates how we have conjoined the two models and used the process of scientific reasoning merged with the strategies of discourse to create a cognitive architecture by which BROCA melds scientific reasoning with the rhetoric of science. Basically, we specify the problem spaces (data, information, knowledge) as arenas for exercising scientific thinking and the state transitions as discourse manipulations necessary to create a tangible, codified "belief structure" which will be passed up the ladder of abstraction as a value-added artifact to be operated upon in the next higher-level workspace.

We have modeled the process as three problem-spaces (data, information, knowledge) and three state transitions (prewriting, writing, revision). Manipulations within each of the problem-spaces requires its own specific set of heuristics. For example, within the data workspace, the thinker is basically examining evidence against a set of goals or expectations. This guided exploration involves a set of procedures or rules-of-thumb by which the thinker sorts out the noise from the data. Methods guiding the exploration are an established set of principles that the thinker has learned, either formally or informally.

3.1 Teaching Scientific Thinking Skills Using Computer Mediated Writing

BROCA performs the role of a mentor by mediating the process of scientific reasoning from beginning (data collection) to end (written report containing "new" knowledge). Using visualizations of what might otherwise be opaque mental operations, the software guides the user through (1) collection/evaluation of evidence, (2) comparing data with theory, (3) formulating and testing hypotheses, (4) interpretation of results, (5) validation through replication. These complex mental activities take place within the framework of a second multi-dimensional, staged cognitive task -- that is, producing an acceptable piece of scientific prose (journal article, lab report, scientific journalism). Embedded within this authentic task are the profound acts of understanding necessary to transform observations into prose, or to move from data to knowledge.

Figure 2: Theoretical Foundations of BROCA

Returning to [Fig. 2], we can map the learning activities supported in BROCA onto this cognitive framework. Each of the five content modules in BROCA follows a basic pattern of guided-inductive reasoning, building an enriched "belief structure" in three central stages:

- *Stage One: Observations and Judicious Collection of Data:* The learner explores a set of basic elements in a domain and formulates a question of interest. Early cognitive activities include using language – as written artifact and as structured oral discussion to (1) capture a "rich" representation of the problem's dimensions, (2) discover what the learners know about the problem, (3) isolate gaps in understanding and anticipate where the learners are weak in background, and (4) develop a plan for continued focused inquiry. Also, the students will learn how to keep an observation journal and to record both affective impressions and objective observations (and to distinguish between the two). These "written artifacts" are essential in finding a solution and must be at least partially completed before moving to the next level.

- *Stage Two: Establishing Relationships and Testing Them against Principles:* Having completed the task of establishing a research agenda (investigation plan) and having constructed information artifacts pertinent to the investigation, the learner is guided through the process of creating information from data. (Since the model is recursive, the learner – in creating this next-level artifact – may notice gaps (missing or incorrect data) and will need to return to the collection/observation phase to remedy this. Generalized activities include observing features, identifying potential patterns, accounting for anomalies, and providing tentative explanations (hypotheses). These "reasoning activities" are mediated by a set of writing and visualization-based heuristics for enabling thinking. For example, the learner is taught how to use "concept mapping" to try out various orderings and relationships in the body of initial observations.

- *Stage Three: Establishing Superordinate Concepts and Presenting Solution(s):* Knowledge is more powerful than information in that it has predictive or explanatory value and can be integrated into a known body of "givens." In the third stage of each BROCA module, students must prove their hypothesis and

BEST COPY AVAILABLE

construct an acceptable knowledge artifact. In short, after exploring the subject domain (data) and working out a richly interconnected "belief structure" drawn from these explorations (information), the learners must shift their attention to constructing a textual artifact that meets a set of external constraints and social expectations. Visual algorithms (thinking frames) and adaptive prompting help students to (1) prune away extraneous or erroneous elements from the problem-space, (2) accomplish critical "state transformations" for information structures – such as clustering specifics and making superordinate categories, and (3) link new knowledge with prior knowledge.

4 Summary and Conclusions

This paper describes the conceptual design of BROCA, a computerized environment to merge the "language" of science with the manipulations, observations, and calculations fundamental to scientific reasoning. Inherent in the discussion are three overarching assumptions about the design and development of advanced educational technologies. First, the design of automated systems should be rooted in cognitive science and educational theory. Advanced instructional technology holds great promise; however, to truly move beyond pale imitations of existing educational media, designers must harvest the rich insights on how humans think and learn already established by cognitive psychology. Second, complex, multi-staged problem solving (in this case, scientific thinking) is an amalgam of visual and verbal symbol usage. By concurrently performing the manipulative/observational tasks along with the consolidative/interpretive tasks, the learner integrates both lower and higher level intellectual processes, as well as concrete and abstract forms of mentation. Third, highly sophisticated, interactive learning environments are possible without using the typical intelligent tutoring system (ITS) approach of constructing a student model, a domain knowledgebase, and an interpretive expert system. By employing cognitive task analysis, the system designer can model the process of the domain and embed adaptive help within the user's performance of the task. Such "cognitive tools" are just emerging as serious competitors to the more traditional approaches to adaptive pedagogy in interactive systems

Abstract - Hypermedia environments have been pointed out as potentially successful sources for learning, particularly to the acquisition of complex knowledge. However some problems have arisen related to orientation: users either felt lost in hyperspace or they couldn't cope with a great amount of information.

We used a case-based approach to foster complex knowledge acquisition and to analyse user orientation or disorientation. Learning is measured in how much knowledge is transfered to new situations. An experimental study has been conducted and is described. Results about knowledge transfer and user orientation are available.

Introduction

Hypermedia environments have been pointed out as potentially successful sources for learning, due to its non linear organisation of information, the use of several communication supports such as text, video, sound, graphics and pictures, and the possibility to choose different paths according to user interests or needs (Conklin, 1987). Studies show that users feel lost in hyperspace and others can't cope with huge amounts of information (Conklin, 1987; Edward and Hardman, 1989; Kim and Hirtle, 1995). Some investigators suggest that learners who are in an introductory phase of any subject do not take advantage in learning from hypermedia environments (Spiro and Jehng, 1990). These environments are more suitable to the acquisition of complex knowledge.

Complex knowledge

When we look at very complicated systems we generally find that the basic components and the basic laws are quite simple; however the complexity arises because many of these simple components are interacting simultaneously and there is a myriad of possible ways in which the components of the system can interact (Waldrop, 1992). Therefore, the whole is more than the sum of its parts.

Advanced knowledge acquisition implies learning complex conceptual material (Spiro et al., 1988). The learner must attain a deep understanding of content material, reason with it, and apply it flexibly in diverse contexts. However some obstacles arise to advanced knowledge acquisition that include conceptual complexity and the increasing ill-structuredness. By ill-structuredness Spiro et al. (1988) mean that many concepts are interacting contextually in a case and their patterns of combination are inconsistent across case application of the same type. This opinion is shared by Waldrop (1992) when he states that in a truly complex system the exact patterns are not repeatable, in spite of the existence of recognizable themes; for instance, in history we can talk about revolutions, even though one revolution might be quite different from the other.

Advanced knowledge learning has significant context dependent variations, and requires the ability to respond flexibly to "messy" application situations, so compartmentalizing knowledge, presenting clear instances and employing reproductive memory criteria are often in conflict with this kind of knowledge (Spiro et al., 1988). Oversimplification of complex and irregular structure, overreliance on a single basis for mental representation, on "top down" processing, context-independent conceptual representation, on precompiled knowledge structures, rigid compartimentalization of knowledge components, and passive transmission of knowledge reduce important aspects of complexity (Spiro et al., 1988; Feltovich et al., 1993). Rand Spiro and his colleagues suggest some solutions to deal with complex knowledge through Cognitive Flexibility Theory. It is important to demonstrate complexities and irregularities and to show how the superficially similar is dissimilar and how superficial unities are broken. Cognitive flexibility involves the selective use of knowledge to adaptively fit the needs of understanding and decision making in a particular situation: knowledge assembly depends on having available, as full as possible, a representation of complexity to draw upon. Multiple representations are important because knowledge that will have to be used in many ways has to be learned, represented and tried out in many ways. Cognitive flexibility depends upon having a diversified repertoire of ways of thinking about a conceptual topic.

Deficiencies in the learning of complex material that are widespread and widely recognized include three major types: misconceptions and incorrect knowledge, the inability to flexibly apply knowledge in new situations, and the lack of retention of knowledge that was acquired at an earlier time (Feltovich et al., 1993). Deep and useful understanding of complex educational subject matter is not commonplace (Feltovich et al., 1993). Educating and testing for understanding of complicated material may require special, directed effort that is so resource consuming that it cannot be applied widely across the many concepts of a given curriculum (Feltovich et al., 1993). New visions of instruction and assessment are required if education is to promote deep understanding of complex, difficult subject matter (Feltovich et al., 1993).

Various forms of failure in advanced knowledge acquisition are frequently associated with traditional learning and instruction. Cognitive Flexibility Theory emphasises the importance of repeated presentations of the same material in rearranged instructional sequences and from different conceptual perspectives (Spiro and Jehng, 1990). This theory claims a case-based approach and generalizes Wittgenstein's metaphor of the criss-crossed landscape. By criss-crossing conceptual landscapes, interconnected knowledge structures are built that permit greater flexibility in the ways that knowledge can potentially be assembled for use in comprehension (Spiro and Jehng, 1990). Flexible learning environments permit the same items of knowledge to be presented and learned in a variety of different ways and for a variety of different purposes (Spiro et al., 1991).

Learning is not a passive process of receiving information; it is rather an active process of constructing new knowledge and incorporating it into what is already known (Feltovich et al., 1993). Knowledge is in many ways bound to the contexts in which it is learned. Conceptual knowledge should be acquired in close coupling with its application and use (Brown et al., 1989).

Case-based approach

A case represents specific knowledge tied to a context and it teaches a useful lesson when it exemplifies a new way of doing something or a new effect that is likely to be useful in later reasoning (Kolodner and Leake, 1996). Cases can came in many different shapes and sizes, covering large or small time slices (Spiro and Jehng, 1990; Kolodner and Leake, 1996).

New solutions are generated not by chaining, but by retrieving the most relevant cases from memory and adapting them to fit the new situations (Leake, 1996). Reuse of prior solutions helps increase problem-solving efficiency by building on prior reasoning rather than repeating prior effort. Cases make it possible to interpret open-ended and ill-defined concepts (Kolodner and Leake, 1996). Reference to previous similar situations is often necessary to deal with the complexities of novel situations; thus, remembering a previous case to use in later problem solving and integrating that case with what is already known is a necessary learning process.

Situations (problems or stories) are interpreted by comparing and contrasting them with previous similar situations and learning happens as part of the process of integrating a new case into memory (Spiro and Jehng, 1990; Kolodner, 1993). Cases need to be decomposed and represented along many partially overlapping dimensions, i.e., the same information must be represented in lots of different ways and many connections must be drawn across the decomposed cases, thus establishing many possible routes for future assembly (Spiro et al., 1987).

We applied cognitive flexibility theory that uses a case-based approach to a hypermedia environment and as complex knowledge we selected a 19th century portuguese novel: *O Primo Basílio*, written by Eça de Queirós.

Description of the hypermedia: "*O Primo Basílio*: múltiplas travessias temáticas"[1]

---

[1] "*Cousin Basilio*: multiple thematic criss-crossing".

This hypermedia offers to the user the opportunity to learn about the novel *O Primo Basílio* through different paths, all of them contributing to the construction of new and multifaceted understanding.

On the Main Menu (see figure 1) several options are available: "View Cases", "Special Topics", "Thematic Criss-Crossing", "Table of Contents" and "Quit".

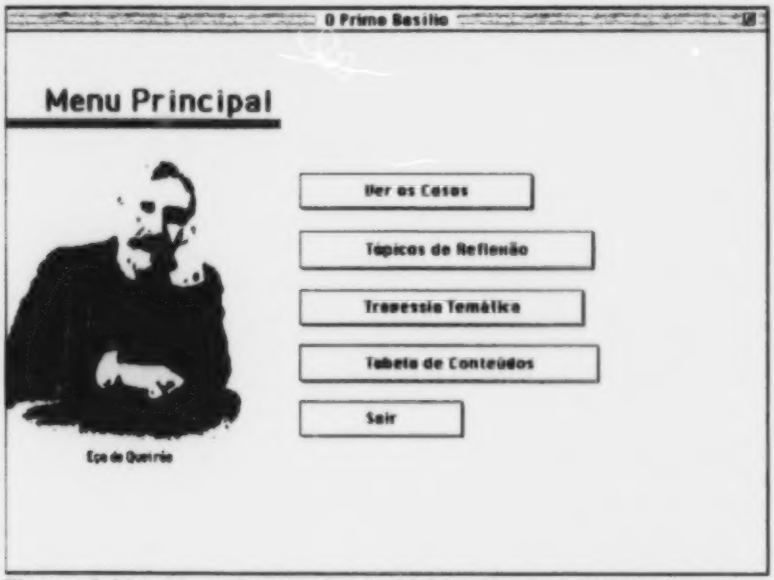

Figure 1. Main Menu of the hypermedia "*O Primo Basílio*: múltiplas travessias temáticas"

This hypermedia presents five cases and nine themes, i.e., nine thematic dimensions of analysis (see figure 3). These cases are sequences of the novel and they are analysed from the perspective of nine different broad scope and partially overlapping thematic dimensions of analysis. A general description of each theme is given when the button (see figure 3) "Descrição dos Temas" is selected.

Each case has small units referred to as mini-cases (see figure 2). Each mini-case presents information about the 19th century to the user (first button: "C" stands for "Context") that may help to recreate that time and helps to understand the text. The fourth button "Thematic Commentaries" provides a list of the relevant themes as its thematic commentaries which describe how the conceptual themes are tailored to the particular mini-case.

The user[2] has access to information about his path on the second button "Navigation Orientation".

The following button (3rd) gives access to a general "Themes Description", and the fifth button allows the user to write his own "Notes".

In "Themes description" and in "Thematic Commentaries" some authors are referred to or quoted, so a button "Referências" with the full references is available. The pictures and movies provided in this hypermedia present information about that time like furniture, vehicles and places, or even songs that are symbolic in the novel.

On each mini-case the user has always information about the name of the case in the bare (see figure 2) and the name and sequence of the mini-case, for example, "1. As leituras". Spiro points out that the user doesn´t get lost in hyperspace because he is never more than one connection away from the focus of instruction (Spiro et Jehng, 1990).

---

[2] For the purposes of this communication the user or learner will be referred to as he.

Era *A Dama das Camélias*. Lia muitos romances; tinha uma assinatura, na Baixa, ao mês. Em solteira aos 18 anos, entusiasmara-se por Walter Scott e pela Escócia; desejara então viver num daqueles castelos escoceses, que têm sobre as ogivas os brasões do *clan*, mobilados com arcas góticas e troféus de armas, forrados de largas tapeçarias onde estão bordadas legendas heróicas, que o vento do lago agita e faz viver: e amara Ervandalo, Morton e Ivanhoé, ternos e graves (...) Mas agora era o moderno que a cativava, Paris, as suas mobílias, as suas sentimentalidades. Ria-se dos trovadores, exaltara-se por Mr. de Camors; e os homens ideais apareciam-lhe de gravata branca, nas ombreiras das salas de baile, com um magnetismo no olhar, devorados de paixão, tendo palavras sublimes. Havia uma semana que se interessava por Margarida Gautier: o seu amor infeliz dava-lhe uma melancolia enevoada (...), nos nomes mesmo do livro - Júlia Duprat, Armando, Prudência, achava o sabor poético de uma vida intensamente amorosa; e todo aquele destino se agitava, como numa música triste,

Figure 2. Mini-case "As leituras" from the case "A vida burguesa"

In the path "View Cases", each mini-case is deconstructed through several thematic commentaries that explain how a general theme is applied to the particular text. The reconstruction of knowledge implies its previous deconstruction. Flexibility in applying knowledge depends on cases being disassembled so that they may later be adaptively reassembled (Spiro et al., 1987).

With the path "Special Topics" the investigator suggests five topics. For each topic relevant mini-cases and thematic commentaries were preselected. The user does a specified traversal among cases and themes that are important to understand the suggested topic.

In the path "Thematic Criss-Crossing", in portuguese "Travessia Temática" (see figure 3), the user may select the theme(s) and case(s) he is interested in. It is a free exploration of themes and cases according to the user's interests or needs.

Both paths mentioned previously promote awareness of representation of complexities and multiple connections across cases. The user criss-crosses the "landscape". The difference between both paths is on user control: in "Special topics" a predefined path is offered, while in "Thematic criss-crossing" the user is free to choose its own.

The "Table of Contents" presents all cases, its mini-cases and its applied themes. From this table, the user can have access to any mini-case she wants.

Figure 3. "Thematic Criss-Crossing"

Problem and Research Questions

Hypermedia environments have seduced educators in order to develop learning applications, however some problems arise with cognitive overload and users' desorientation. Cognitive flexibility theory proposes a theory of learning and knowledge representation to foster the acquisition of complex knowledge.

Several studies pointed out to good results when cognitive flexibility theory is applied (Jacobson, 1991; Jacobson et al.,1995; Torres, 1995; Moreira, 1996). We intend to validate this theory in a portuguese context and we are also interested in verifying Spiro and Jehng's (1990: 201) statement about the user's orientation: he "can never get lost".

We intend to answer these main research questions:

- How important is "thematic criss-crossing" in knowledge transfer?
- How important are "thematic commentaries" in knowledge transfer?
- Does the user get lost in hyperspace?

Method

Three treatments are considered in this study, that imply three slighty different hypermedia.

Hypermedia 1 (CFT)	Hypermedia 2 (NCC)	Hypermedia 3 (NTC)
Themes description	Themes description	Themes description
Thematic commentaries	Thematic commentaries	Applied themes
Oriented Thematic criss-crossing	Thematic criss-crossing designation only	Oriented Thematic C-C. (no thematic commentaries)
Free thematic criss-crossing		Free thematic criss-crossing
Table of Contents	Table of Contents	Table of Contents

Table 1- Comparison of three treatments

The first treatment applies the principles of cognitive flexibility theory and is the hypermedia described previously.

The second hypermedia is similar to the previous one, but it has no facilities to criss-cross the information (**No Criss-Crossing** available).

The third hypermedia doesn't explain how a particular general theme applies to a particular text, i.e., it has no "Thematic commentaries", but only the designation of themes that apply (**No Thematic Commentaries** available).

All groups spent 3 hours per day, twice a week, during two weeks, working with a hypermedia and doing tests (see table 2). All subjects should have read the novel before starting the study.

Session 1	**Session 2**	**Session 3**	**Session 4**
Subject information sheet	Hypermedia		Hypermedia
Pre-test (A)	Test B	Hypermedia	Post-test (C)
Hypermedia document	Questionnaire of opinion		Opinion Questionnaire

Table 2- Sessions structure

Subjects answered the three knowledge tests: pre-test (A) was done before they started working with the hypermedia, test B during the second part of session 2 and Post-test (C) at the end of session 4. Differences between the three groups were measured on how much transfer each group produced.

Subjects orientation or desorientation and opinions about the hypermedia were measured through an "Questionnaire of opinion".

Sample

Subjects were 3rd year university students, of Portuguese language and literature, volunteers (see table 3). Each group was randomly assigned to each treatment.

	Hypermedia 1 CFT n=16	Hypermedia 2 NCC n=14	Hypermedia 3 NTC n=12
Female	14	13	11
Male	2	1	1
Age (average)	22	22	21

Table 3. Sample characterisation: age and gender.

As the number of subjects by group is too small, non-parametrics tests were used and the accepted significant level is α=.05.

Results

All groups learned significantly from pre-test to post-test: group CFT p=.0004; NCC p=.001 and NTC p=.0022, according to the Wilcoxon signed-rank test.

Statistically significant differences were found among the results of the three groups pre-test, using Kruskal-Wallis test, p=.0009 (mean rank - CFT: 27.25; NCC: 11.57; NTC: 25.42). As the group responsible for this statistically significant differences was the NCC, and the subjects of this group didn´t finish reading the novel as recommended, we decided to compare the CFT and the NTC groups. Pre-test results revealed no statistically significant differences between CFT and NTC groups, p=.6091. These groups revealed statiscally significant differences p=.0071 (Mann-Whitney U test) on post-test (C) .

When comparing post-test/pre-test gains (score 0-20) no statistically significant differences were obtained p=.1009, but group CFT appears on the first place with 8 points, group NCC with 7,5 points and group NTC with 6 points.

Test B revealed a statistically significant difference p=.0160. The order of distribution of the three groups in Test B and C is the same (see figure 4), but there are only statistically significant differences with test B among three groups and groups CFT and NTC in test C.

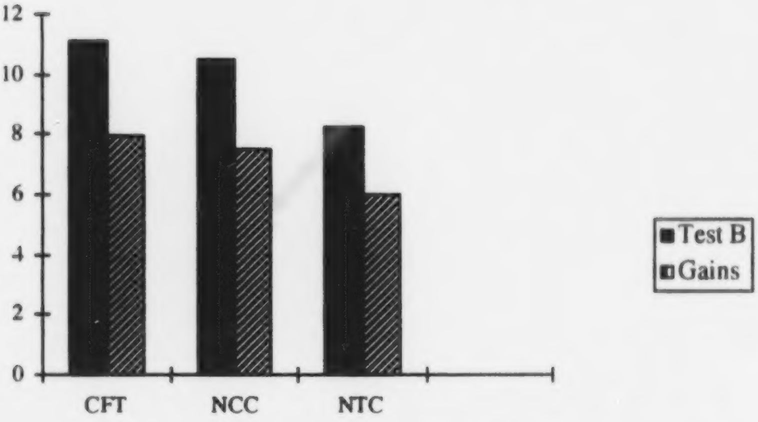

Figure 4. Distribution of Test B and gains.

We may conclude that CFT hypermedia, with all its paths that allow different knowledge representations, is the most effective way of learning. "Thematic commentaries" are responsible for statistically significant differences between groups CFT and NTC. Oriented "thematic criss-crossing" versus "thematic criss-crossing designation only" didn't allow statistically significant differences, and "Thematic commentaries" were responsible for similarities in the results between groups CFT and NCC. In this study we may conclude that "Thematic commentaries" are more important than "thematic criss-crossing" to knowledge transfer to new situations.

At the end of this experiment we offered to groups NCC and NTC the opportunity to see and compare their hypermedia with CFT hypermedia: the two groups had different reactions. Group NTC realized that a lot of information was missing and they would easily answer the tests if they were working with CFT hypermedia. Instead, group NCC prefered their hypermedia because they had to be involved and tried to answer the proposed "thematic criss-crossing designation". Besides, they enjoyed this challenge.

During session 1, according to "Questionnaire of opinion", 50% of subjects felt lost in the hypermedia but on the second session this feeling disappeared, as it could be expected based on Spiro and Jehng's (1990) statement. Subjects enjoyed the study of "*O Primo Basílio*" on the hypermedia and they referred that it would be interesting to have other hypermedia to study other subjects during their courses, because "*in a few hours we learned a lot!* " .

Abstract: This paper introduces a conceptual high level design model for HyperStories and HHCASE, a CASE tool that supports and facilitates the building of HyperStories. HyperStories are stories that happen in a virtual and interactive hypermedia environment. The model and tool consider static and dynamic aspects of the hypermedia environment such as the modeling of contexts, interactive entities and navigation. HHCASE also allows to define links between different components of a HyperStory. Finally, relevant issues related to the construction of HyperStories are discussed.

1. Introduction

An emergent line of research and development on hypermedia learning is proposing new ways of producing software to really help learners to learn and think [Ambron 90; Jonassen 90]. Adequate use of hypermedia software may change the way learners normally think by putting flexible tools in their hands to stimulate them to think about relationships. To support this, we have proposed HyperStories [Sánchez 94; Sánchez 95; Sánchez 96; Cernuzzi 94] a new educational paradigm that merges the idea of stories with hypermedia functionality to produce dynamic and flexible software to exercise thinking while acting, playing, exploring, navigating, and having fun. The idea of hypermedia based stories is not new, some ideas were first introduced at the beginning of this decade. However, we consider that more effort should be spent to reach the really educational potential offered by the conjuntion of stories and hypermedia capabilities through a robust model. HyperStories explore new horizons in the use of stories as a mean for helping young learners to construct and reconstruct their thinking structures [Carter 93; Egan 86; Coles 89; Applebee 78; Frisher 88]. HyperStories can be seen as the electronic version of conventional literary stories. By taking the advantages of multimedia technology learners are given a rich environment of contexts, characters, objects and their behavior, links with navigational tools, and friendly interfaces. This involves important tools that can be used to construct and reconstruct learning and cognitive structures. When the learner is engaged with HyperStories, she/he navigates through contexts, manipulates objects, interacts with characters, identifies her/himself with a main character called *protagonist* and moves freely through a familiar virtual world.
Conceptually, we can define a HyperStory as:

HyperStory = Hypermedia + Dynamic Objects + Protagonist

Hypermedia is in charge of representing the environments and the links among them. The dynamic objects are entities with a defined behavior and may react according to the events generated by the learner or other entities. Objects and characters may have their own behavior and act autonomously, eventually influencing the development of the HyperStory. The protagonist is manipulated by the learner and represents the connection between her/him and the system. Furthermore, the learner can also interact with other characters or objects in order to solve a given problem. In doing so, the learner can strongly control the HyperStory. In the below sections, we explore more deeply the constituing elements of HyperStories and introduce a new high level design model and a CASE tool.

2. Designing Hyperstories

Traditional hypermedia design models are inadequate to capture and model several flexible and interactive aspects of HyperStories. In addition, conventional hypermedia authoring tools do not provide an adequate set of facilities for building HyperStories. For this reason, a specially defined conceptual model was presented in [Sánchez 94; Sánchez 95]. The model allows designers to capture and model static environments and dynamic objects by providing a powerful description language that merges ideas from object and context oriented approaches.

However, this model is probably more accessible to designers with programming skills. Hence, in the present work we focus on the high level design process of HyperStories trying to offer more easy-to-use facilities to a wide number of potential authors. Below, we present some HyperStory elements and introduce a conceptual high level design model for HyperStories capturing those elements and their relationships. Then, we present a tool to support the model.

2.1 HyperStory Elements

Many elements compose a typical story, as well as a HyperStory. Here, we want to focus on the script - that may stimulate the learner's motivation and involve her/him in a constructive behavior -, environments - representing the virtual world of the story - and entities.

Script: a Hyperstory, like any other story, has a script. However, while a regular story script is typically fixed and linear, a HyperStory script is dynamic and non-linear. In effect, in HyperStories there exist a surrounded basic script that can be strongly influenced and enriched by autonomous behavior of some entities. Specially, decisions of the protagonist manipulated by the learner may change the progress of the HyperStory. In some way, we can state that the protagonist "is" the story.

This property is presented every time the HyperStory offers the learner the opportunity to choose between alternative paths. These paths may be static (previously defined by the designer) or dynamic (generated by entitiy interactions) and may be explicit or not, thus allowing alternative stories.

Environments: an environment represents the context in which actions occur, and the group of the environments represent the virtual world of the HyperStory. So, the entities, specially the protagonist, may move freely through them complaying with particular restrictions. Normally, these environments are inactive and static, although entities participating may change in time and modify their appearance (e. g. a light can be on or off).

Entities: are objects (animated or inanimated) present in the environments. A special entity is the protagonist, manipulated by the learner. Entities may be active, may move themselves, may have autonomous behavior, act concurrently, interact between them, and alter the environments. In a typical HyperStory, entities are characters and all those objects that are critical to the story. Entity actions are responsible for the HyperStory progress and the course of the progress. In effect, entities influence the protagonist in choosing the path through multiple directions offered.

2.2 HyperStory High Level Design Model

Once the main elements of a HyperStory are described, we introduce a high level design model capturing these elements and their possible relationships.

HyperStory Script (HS): is the composition of a basic plot, with eventually concurrent and partially independent scripts (representing different actions assigned to the characters) and possible protagonist (user) interaction specified in an informal textual language.

HyperStory Flow Diagram (HFD): is in charge of capturing the HyperStory script. Basically consists of a set of shapes connected by edges. Every shape represents a portion of the HyperStory script, a stage in the HyperStory [Fig. 1]. The edges represent the *next* relationship between different portions of the script. The next relationship has N:M cardinality. It is possible to activate different stages of the HyperStory from a particular one (represented by multiple output edges from that shape). A stage could be activated by different ones (represented by multiple input edges to that shape). Shapes and their semantics are similar to that used in data flow diagrams of conventional structured analysis and design. The separation criteria for the stages of the HyperStory is made by the designer and may help to gain a better understanding of the HS.

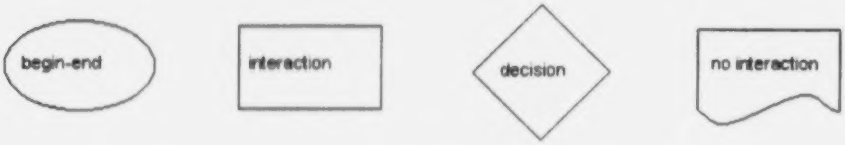

Figure 1: Shapes availables to define HFD

HyperStory Contexts Diagram (HCD): represents all the environments in which the HyperStory occurs and the different relationships among them. Environments are defined through descriptions given by the author and based on a contextual approach. There may exist different relationships between environments. The three we consider more interesting are: ***neighborhood*** (N:M, many environments could be neighbor to many others), ***inclusion*** (1:N, one environment could include many others) and ***perspective*** (1:N, one environment could have different perspectives). Different environments are neighbors if it is possible to have movement between them (e.g. the kitchen is neighbor to the garden and it is accessible crossing a door). Neighborhood is not permanent and not necessarily implies physical adjacency. For example, in a specific moment of the HyperStory it may be impossible to access the garden from the kitchen because the door is locked.
The inclusion relationship allows the designer to represent the inclusion of one environment into another (e.g. a room is included in the house).
Finally, the perspective relationship, similar to the idea presented in [Garzotto 93], allows the designer to represent the same environment from different views (e.g. the dinner room viewed from the kitchen or from the hall, or the dinner room with the light on or off). Environments are modeled by circles and each edge model a relationship. The type of relationship is represented using different colors or line styles for the edges. Furthermore, it is possible to associate a label to the edges in order to specify the navigational semantics, the events that activate the link (e.g. for a neighborhood relationship, the edge may be labeled with the connecting object, such as a door), and eventually constraints to traverse it.

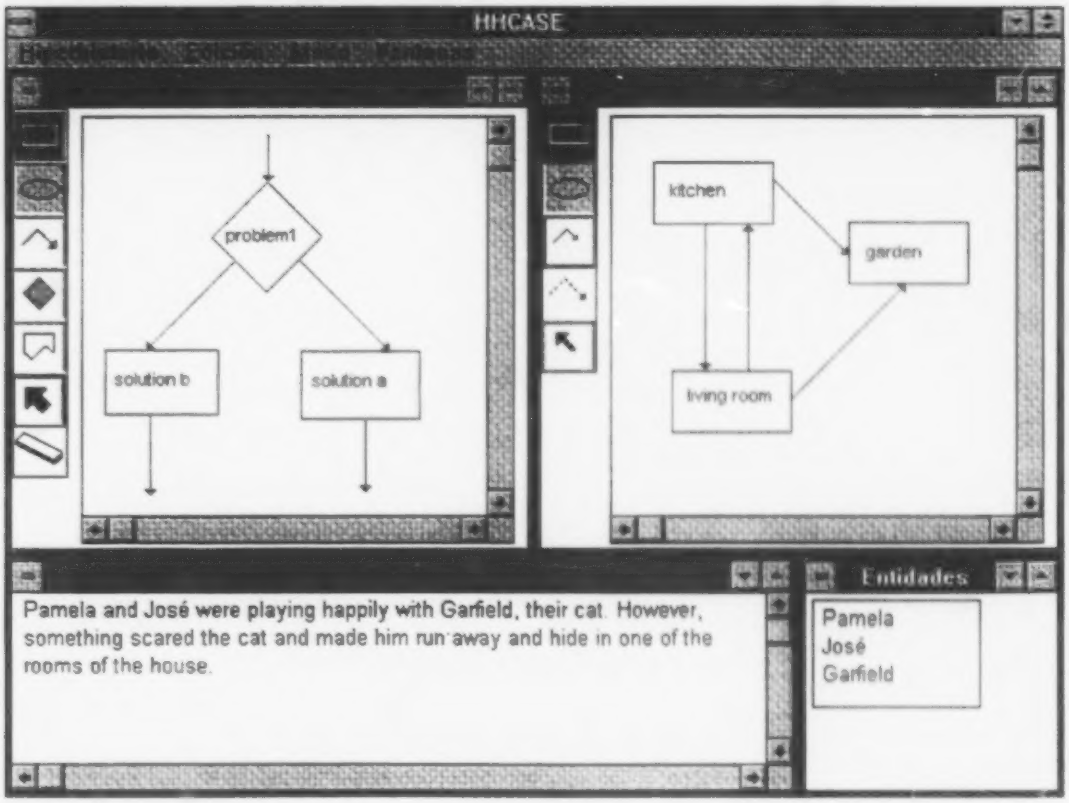
HyperStory Entities (HE): model all defined characters and objects. Similar to the HS, entity behavior and properties can be specified in an informal textual language. They strongly contribute to the resulting HyperStory script.

Many other relationships may be given between specified elements. One of the most useful relationships from a navigational perspective is ***environments-navigability***, which does not directly match with ***the neighborhood-inclusion*** relationships previously defined. It depends on the portion of the HS active in a particular instant (e.g. the kitchen door may be open or closed in different times) and on some entities (e.g. the cat can access the garden through the window but the mother cannot). The set of links modeling all environments-navigability relationships capture hypermedia characteristics and allows the end user to explore different contexts of the HyperStory. The exploration metaphor is very powerful and stimulating for educational purposes. It introduces a difference respect to conventional hypermedia systems, for which navigation is oriented towards search information, that is, a contents-oriented browsing. On the another hand, by exploring the environments, learners may acquire useful information to solve a particular problem or, simply, to recognize the virtual world. In this way, navigational semantics assume a very important role for learner motivation and it is desirable to allow the designer to simplify the specification
Another interesting relationship is ***entities-participation***. It relates the HS to HE and allows designers to specify which entities participate in every stage of the HyperStory. Hence, every entity (active or not), participating (directly or not) in a stage of the HyperStory, collaborates to the story progress.
Furthermore, it is important to specify what contexts are involved in a particular stage of the HyperStory. We call this relationship ***environments-participation***.

One of the mayor problem in designing HyperStories is that they are intrinsically dynamic. Therefore, environment-navigability, entities-participation and environments-participation could result in flexible relationships that may vary depending on time, entities' behavior and learner's interaction. This represent a good example of "dynamic link" problem, pointed out in [Kendall 96; Hardman 93], and we leave deeper consideration on the topic for future works.

3. HHCASE: a New Design Tool

HHCASE is a tool that allows the HyperStory designer to model and possibly reuse HyperStory scripts, entities, environments, and all the previously defined relationships among them. Conceptually, HHCASE is composed of several windows containing diagrams and text, and a set of facilities to create and maintain different kinds of relationships represented by links.
HHCASE is strongly based on the model previously defined and presents a main window and a set of windows which correspond to the four elements described above: HFD, HCD, HE, HS[1]. In particular, HFD and HCD, have associated toolbars that help their edition [Fig. 2].



Pamela and José were playing happily with Garfield, their cat. However, something scared the cat and made him run away and hide in one of the rooms of the house.

Pamela
José
Garfield

Figure 2: Main window and windows defining elements in HHCASE

Furthermore, HHCASE provides a unique and easy way to instantiate different types of relationship. Independently from the relationship type, the process consists of selecting the participant elements for the relationship and adding the relationship to the HyperStory by menu, keyboard or toolbar.

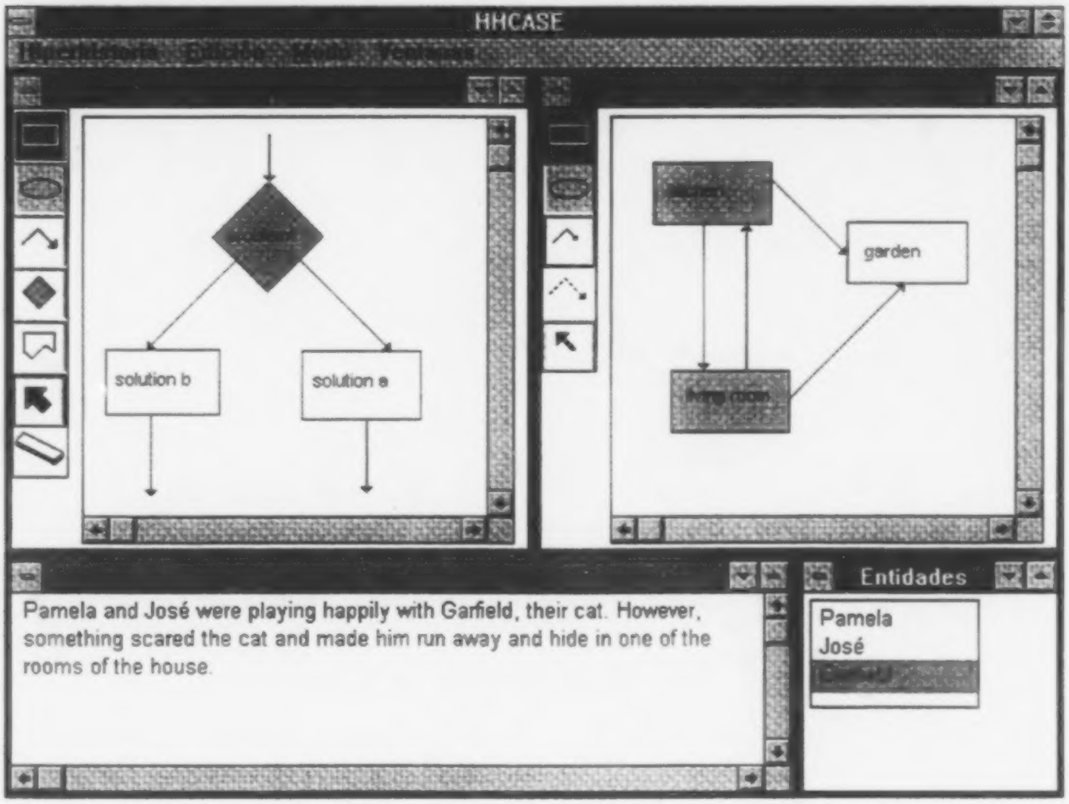
---

[1] Names appearing in figures correspond to the spanish version of HHCASE.

BEST COPY AVAILABLE

Hereinafter, we present the different types of relationships supported by HHCASE and their semantics:

- *Next*: two elements of HFD representing what is the immediately next stage of the HyperStory
- *Neighborhood, inclusion* and *perspective* among elements of the HCD
- *Environments-participation*: one element of the HFD with a set of elements of the HCD; modeling where contexts are active in a stage of the HyperStory
- *Environments-navigability*: one or more entities of the HS, one element of the HFD and a set of elements of the HCD modeling where entities may navigate through specified contexts in a specific stage of the HyperStory [Fig. 3];
- A relationship between one element of the HFD and a portion of HS modeling where a part is active in a specific stage of the HyperStory.



Pamela and José were playing happily with Garfield, their cat. However, something scared the cat and made him run away and hide in one of the rooms of the house.

Figure 3: Example of *Environment-navigability* relationship

Each relationship can be enriched by textual comments allowing designers to better specify the semantic relationship and eventually Pre-Post conditions. For example it is possible to state that the garden is accessible from the kitchen if the precondition is true: the character has the key.

Finally, we consider that HHCASE provides some interesting qualities:

- modularity and separation of concerns, implemented using different windows and menus;
- enough rigor, provided by well defined elements and relationships;
- flexibility, mainly provided by textual comments;
- ease of use, coping with the special requirement that normal designers may not be programming experts.

However, specification rigor gives designers and developers a unique language with a clear semantic, eventually enriched by comments, facilitating the interface between the design and implementation processes.

4. Conclusions and further work

In this work we have presented a conceptual model and a CASE tool for designing HyperStories, a modern paradigm to enhance higher order cognitive skills by thinking while playing, exploring, navigating, and having fun. In many aspects, such as interactio, navigation through virtual worlds and challanges, the reader may note a close relationships between this proposed metaphor and MUDs environments. However, MUDs differ from HyperStories because does not have an explicit model and a narrative closure. Moreover, MUDs narrative is less intentional the HyperStory one. HyperStory may be seen as a subclass of MUDs. That implies substantially differences in conceptualization and design approaches. Nevertheless, HHCASE may be used to capture and model some of the critical aspects of MUDs. Designing HyperStories is obviously not trivial and comparatively more complex than designing other hypermedia-based educational software [Cernuzzi 94].
We consider that the present work represents a step toward a better comprehension of HyperStories rhetoric. Moreover, the high level design model and HHCASE provide some interesting advantages for designers without programming skills. They support the domain analysis, and consequently the evolution process from a story to a HyperStory, by providing a framework that facilitates an easier and exhaustive identification of different components of a HyperStory whitin a structured process.
From this perspective, we consider that some directions covering pedagogical-technical themes may be explored in further works. Some of these may be: 1) an enhanced version of both model and tool to cope with dynamic evolution of the HyperStory; 2) the improvement of the tool to better specify semantic relationship and to eventually introduce new relationships in a easy-to-use environment; 3) the use of HyperStories in different contexts as well as a much deeper formative and summative evaluation and 4) the construction of new tools covering the gap between the design and implementation process.

Abstract: This paper traces the process of repurposing a sophisticated multimedia CBT program, the "System for Training Aviation Regulations" (STAR), built originally for aviation maintenance technicians, into an on-the-job training aid for aviation safety inspectors. Three flexibility issues confronting curriculum developers are addressed within the context of this analysis and several conclusions are drawn from our experience with repurposing the STAR program.

Introduction

This paper traces the process of repurposing a sophisticated multimedia CBT program, the "System for Training Aviation Regulations" (STAR), built originally for aviation maintenance technicians, into an on-the-job training aid for aviation safety inspectors. Three flexibility issues confronting curriculum developers are addressed within the context of this analysis. These flexibility issues are:

- modifying the training program to fit a variety of training needs and audiences,
- keeping the training program current, and
- designing a program that continues to meet the needs of individuals as they mature into their job.

STAR-AMT

Target Audience

The training program for aviation maintenance technicians includes a course about the Federal Aviation Regulations (FARs) and document research. The material is dry, not intuitively organized, complex in presentation and content, and written in legalese. Instructors have few tools to make the material more vibrant and meaningful, relying heavily on reading passages out of the FARs and discussing their content. As a result, students tend not to see the relevance of what they are studying; they tend to bog down in the details, missing the big picture. The target audience has several defining characteristics. First, the target audience consists of students enrolled in a class usually in a college or high school setting. Second, most are new to aviation. It is within this instructional environment that STAR was developed.

Theoretical Approach

Multiple Vantage Points to Complex Information

There are two aspects to information complexity that have bearing on the instructional process. One is the relative difficulty of an individual concept. The other is the volume of information. In order to state "I understand this concept," or to say "I am an expert in this domain," one needs to be able to integrate components of a concept or domain into a scheme that can be readily demonstrated to others. A key factor to demonstrating conceptual understanding is the ability to identify relevant from non-relevant information. Conceptual schemes help to organize conceptual components and discern the difference between central and peripheral concepts. Taking multiple vantage points to a content area contributes to building conceptual schemes by providing overlapping information where the central themes tend to be repeated.

STAR-AMT is designed to help students acquire the "big picture" about what the FARs role is in Aviation. This is done through developing a conceptual scheme about how the FARs impact the daily tasks aviation maintenance technician's must perform and also what the aviation maintenance technician's role is with respect to complying with the FARs. This is accomplished, in part, by providing many vantage points to the same body of information. Experiencing complex material repeatedly under different circumstances provides multiple opportunities to gain a deep understanding of the subject [Spiro & Feltovich, 1991]. Each vantage point not only covers different aspects of the same material, but also reinforces different kinds of study skills. In this way, students are not only provided with multiple ways of viewing the information, but also with multiple opportunities to learn. In addition, information conveyed through one learning environment may best fit one student's style of learning, while the other learning environments fit other people's learning styles. Thus, more people benefit when multiple approaches to the subject are taken.

Learning in Context

Part of the difficulty in teaching the FARs is that students perceive the subject to be very dry. Indeed, some of the tasks expected of the students can be pretty tedious. However, there are many opportunities to convey the complexity and subtlety of the information in interesting ways. "War stories" from Aviation maintenance technicians currently out in the field is one way to make the material more interesting and meaningful to the student. Stories are well-suited for capturing tacit instructional knowledge, because storytelling is a more natural way for people to convey ill-specified practices [Chandler, 1994].

Another way to make the material more meaningful is to immerse the students in scenarios that confront them with "real world" decisions related to their jobs. By placing the application of the FARs in context, students have a much better chance of constructing for themselves a scheme [Brewer, 1987] for how the FARs operate functionally in aviation. When students are given the opportunity to learn in context, the concepts are acquired more rapidly, durably and are more easily transferred to new situations [Brown et al., 1989]. Both "story telling" and "situated learning" through scenarios place the information to be learned in contexts that the student can more easily relate to and remember.

Media-Rich Presentations

Media-rich presentations are a third approach to making the subject of the FARs more interesting. Multimedia has other pedagogical advantages as well. According to Park and Hannafin [Park, Hannafin, 1993], multiple, related representations improve both encoding and retrieval. Learning improves as the number of complementary stimuli used to represent learning content increases. For example, when concepts are encoded in both verbal and visual forms, they are retained in memory longer and are more easily accessed, because the two types of information complement each other in the activation, representation and development of related information [Park 1994]. Thus, complimentary information presented through multiple types of media is most favorable for conceptual retention.

The Learning Environments

STAR-AMT offers several different categories of learning environments: Overviews, Scenarios, Challenges, and Resources. Overviews give students the overall structure of the FARs and are best viewed first. Scenarios anchor [CTGV, 1992] students in real world situations, and Challenges are designed to promote the integration of material covered in the other learning environments, as well as provide students with a self testing mechanism for assessing their knowledge of the material. Resources are designed to augment and support the activities in the other learning environments. For a more complete description of each learning environment refer to the CD-ROM version of this paper.

The new challenge. Repurposing STAR for Aviation Safety Inspectors

New Target Audience; New Working Environment

In the beginning of April 1996, the STAR research team began to explore whether STAR could feasibly be reconfigured to address the on-the-job training of aviation safety inspectors. This is a very different target user group in a very different training environment. Aviation safety inspectors are experienced. Where the Aviation maintenance technicians were relatively young naive students new to aviation, aviation safety inspector's begin their inspection career after ten to fifteen years of experience in the field. They tend to be older. The average age of an aviation safety inspector is 45. They are specialists. Each aviation safety inspector specializes in one of the following areas: airworthiness, avionics, operations or cabin safety. Aviation safety inspectors are enforcers of the regulations. They must have an intimate understanding of the intent of the regulations and it is assumed that they do. Another significant difference between aviation safety inspectors and aviation maintenance technician students is that Aviation safety inspectors are working. Their primary concern is doing their job. Built into the job is an extensive on-the-job training program for both veterans and new recruits. Flight standards has a well established mentoring program for all new recruits and each new recruit must pass an exam for each inspection before they can perform that inspection unsupervised. Integral to the general atmosphere of pride among the aviation safety inspector community is a collective consciousness of how one should conduct oneself as an aviation safety inspector. This collective consciousness keeps regulatory conduct in the forefront and is vital to overall health of the community.

Despite the extensive on-the-job training program, there are problems. Aviation safety inspectors are expected to handle all types of inspections for all types of aircraft, not just their area of expertise. Veterans often feel hard-pressed to keep up with the field. It is easy to become rusty on inspections they do not do frequently. New recruits are busy learning through work. Because of extensive travel associated with the job, mentors are often not available to new recruits for consultation.

Description of STAR-ASI

STAR for aviation safety inspectors is composed of the same general components as the STAR program for Aviation maintenance technicians. Three of the learning environments, scenarios, resources and challenges, are identical functionally, with new content simply replacing old content. A new learning environment, Inspection Task Flow Charts, has been implemented in place of the Overview learning environment.

Inspection Task Flow Charts

Each inspection is considered to be a task. For their on-the-job training, the airworthiness group has developed task flow charts that show the logical steps for each inspection task, including decision points (e.g. Has a FAR been violated?). By simply implementing these flow charts on the computer, the STAR team has been able to leverage off of the visual representation of each inspection task developed by the airworthiness group to create an interactive version of that representation [Figure 1]. Now a new recruit not only has a visual representation of each inspection procedure, but also can investigate each step in the procedure. All other learning environments can be launched from each step in a task flow chart. Depending on the instructional objective, one has the option to ask a quiz question, show what a form looks like, attach relevant passages from an Order or a FAR Part, comment on what an inspector's responsibilities are, or create a mini scenario. Task Flow Charts give each inspection procedure a structure; the dynamic nature of the computer provides informational depth to that visual structure.

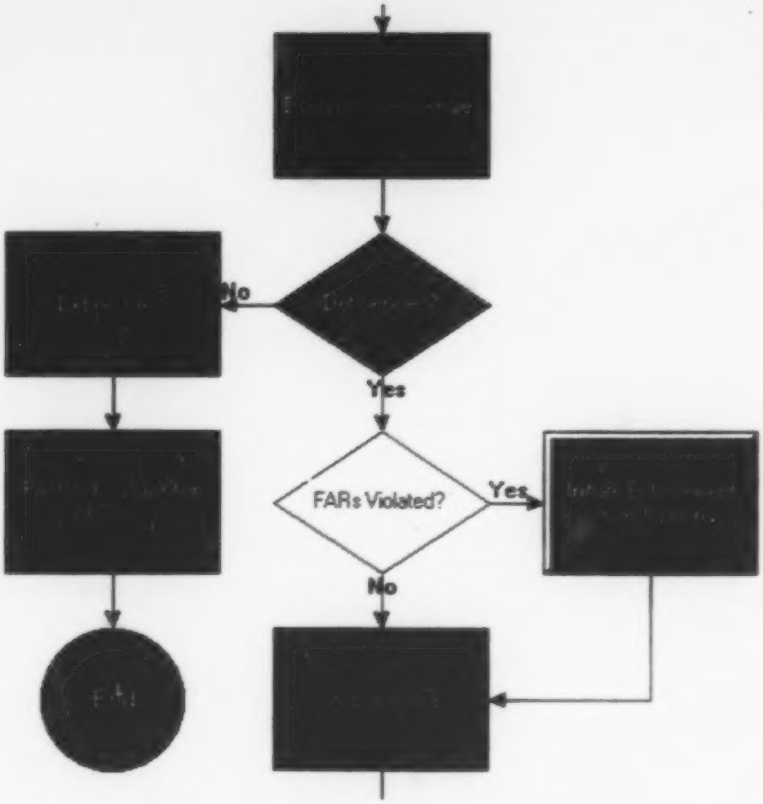

Figure 1: Inspection Task Interactive Flow Chart

The Emphasis

Based on task analysis and numerous discussions with Aviation safety inspectors the team decided that scenarios are best suited for situations where:

- there is a significant amount of interaction between people,
- there are several plausible ways a person can respond to a situation,
- individuals must draw upon a significant amount of their resources or understanding of the situation in order to make the best decision, and
- choosing a wrong answer does not necessarily terminate the story.

The STAR team found that scenarios were much easier to generate for maintenance than inspections. Part of this may have been due to the characteristics of the people who provided the scenarios; part of this had to do with the nature of the two domains. Stories generated for maintenance tended to be about a job that needed to be done and what considerations needed to be made in order to complete the job legally. Many interesting situations could be woven from doing a major repair or conducting a 100 hour maintenance inspection. The story tellers being instructors was another advantage. Part of their job involves weaving stories to make salient points about aviation concepts. Inspectors are more procedurally oriented. They can easily generate "what if" questions (e.g. What if the captain does not have his medical certificate? What if the first aid kit is not sealed?) but often these questions terminate the story with a violation. The highly procedural and primarily linear nature of inspections make weaving an interesting and authentic story more difficult.

BEST COPY AVAILABLE

Interactive Task flow charts have become the center piece of STAR for Aviation safety inspectors in place of scenarios. Because inspections are so procedurally oriented, task flow charts best represent what an inspector needs to consider when doing a particular inspection. Interactive Task Flow charts have certain curricular advantages. They can function as a reference, as well as a guide. In the simplest instance, a step may just have commentary or it may have sample forms available to remind Aviation safety inspectors of what the forms look like and for what purpose they are used. Sections of Orders and FARs relevant to that step (and only those sections) are attached for the Aviation safety inspectors perusal. Where appropriate, the document is structured and highlighted to reveal its most salient points. Legacy data is removed for clarity. These simple features allow Aviation safety inspectors to review the most salient points and information associated with any given inspection.

From Training Aid to Job Aid

For STAR-AMT, resources augments and supports training; for STAR-ASI, the emphasis is reversed - training augments and supports resources [Duchastel et al., 1995-96]. Even in the context of on-the-job training, the primary activity and concern of each aviation safety inspector is having the right information at the right time to do his or her job well. Sometimes that may be learning how to conduct oneself during an inspection; other times it may be reminding the aviation safety inspector which forms are needed for a particular inspection. In either case, STAR is designed to handle both needs. Task flow charts, for example, organize the information into a logical structure. This structure can be used in several ways, depending on the experience of the user and his or her present needs. For a new recruit, the flow chart is a training aid that he or she can step through, see the organization of the inspection, quiz him or herself, look up terms or read relevant documentation; he or she can view what sample forms and review how and to what purpose they are used. A veteran can review the steps of an inspection not done in a while before venturing out into the field. Or they might use it purely as a reference to look up which form they are suppose to use or the meaning of that acronym they never really learned. Scenarios which target new recruits more than veterans might never be touched by veterans. However, a mentor might employ the scenarios as a vehicle for discussions with new recruits.

Keeping Current

In the working world where documents are living and policies change, it is vital to create a CBT that supports this environment. Information and training should be designed so that they can be updated and changed easily. This means a more compartmentalized approach. If a step in the flow chart is no longer relevant, only that part should be changed, not the whole structure. In situations where compartmentalization of information is difficult, as is the case of a long involved scenario, the content should not focus on particulars that are likely to change. Rather, themes such as ethical conduct or procedural issues should be addressed. How one debriefs an organization after the completion of an inspection, for example, addresses an important theme about conduct that effects all inspections and whose message is unlikely to change over time.

Living documents, especially if they are expected to retain legacy data, can be difficult to maintain. It is this kind of information that will date a training system. Electronic publishing techniques could help maintain this kind of information. Electronic publishing structures textual information for different views so that the most relevant points are accessible for a particular audience . For example, legacy data can be hidden behind hypertext references. The history of the document is preserved but it does not obstruct the presentation of the most recent version of the document for training or review.

Conclusion

Four conclusions can be drawn from our experience with repurposing the STAR program. First, it is much easier to build a resource that incorporates training than to build a trainer that some how metamorphoses into a job aid. Second, the system needs to be highly modular. In STAR, for instance, each learning environment (e.g. Resources, Scenarios, Challenges) is self contained; as is each learning module (e.g. the Glossary, the Cabin Enroute Inspection Scenario, the A & P Task). One can swap out a training module, a learning environment, or a reference guide depending on one's training or job aiding needs. Third, applying a browser approach to interface design increases the options for how the system can be used. STAR's browser style interface gives the system the flexibility to be a presentation aid, a self paced tutor or a reference utility. It is not bound to a lock step tutorial approach. Modularity and a browsing style interface give STAR maximum flexibility for accommodating different training and job aiding objectives. Finally, electronic publishing may offer some solutions for training systems that rely on living documents as the basis of their training, but the ongoing battle to keep training programs current will continue to be a battle for curriculum developers.

Abstract: In this paper, we propose a model for managing the learning flow and portfolio to scaffold learners and promote learning efficiency of distance learning environment on World Wide Web. Users' requirements depict the difficulty to promote learning performance when we constructed distance learning environment on network tools. New network technologies attract instructors to adjust the system architecture for better learning performance frequently. Furthermore, designing distance learning environment on existing network tools always made additional burden for instructors and learners. For instance, it may request an instructor to master the network tools for developing distance learning environment and students should pay attentions to acquire the environment. To improve the problem thoroughly, the learning flow and portfolio management of distance learning environment can enable an instructor to scaffold and observe learners' behavior effortlessly. This paper presents a generic framework as well as a software prototype for managing learning flow and portfolio on Web. The framework can promote learning performance, avoid continuous adjusting system, and reduce users' burden.

Introduction

Existing distance learning systems use network tools for educational telecommunication. However, regardless of how good a distance learning system designs, the learning performance mostly depends on learners' interests to the distance learning system. Owing to the popularity and easy access of the computer network and associated communication tools, network facilities can be incorporated into a distance learning system. For instance, learners in a distance learning system can learn by reading hypertext learning materials, discussing, or asking questions through the computer network. Consequently, we applied network tools on the Introduction of Computer Science course to promote learning performance of a realistic class. The initial purpose was to scaffold students by answering questions and to observe students' learning problems on distance. At the beginning, students used mail list to communicate because every student had a UNIX account and electronic mail can 'server as a foundation for strengthening interstudent communication.' [Wissick *et al.*, 1995] The communicating method of mail list is broadcasting to memberships of the mail list by electronic mail. Consequently, all memberships receive all questions and answers by electronic mail. Some teaching assistants were responsible for answering questions because we did not expect others will answer a beginner's questions. We cheerfully found that some students answered trivial questions frequently. Applying mail list did provide students an additional way to learn on distance. However, some problems occur when using group learning strategies to promote the leaning performance of the class. The problems include: (1)*Lack of learning activities for increasing participation.* We tried to increasing students' participation because many students never joined discussion by mail list. We inquired those students and found that most of them are afraid of asking a trivial question or providing an incorrect answer. We divided students into groups for studying topics and sharing reports to resolve this problem because researches revealed that learning performance of a group learning environment depends on proper learning activities [Bricker *et al.*, 1995]. However, applying group learning strategy on existing distance learning system must suit to network tools. (2)*Lack of learning flow for scaffolding learners.* Although mail list facilitates teachers to answer students' questions, mail list can not specify a flow to scaffold learners. For instance, a teacher may want students to submit their homework by email after students familiarized with discussion by mail list. Ideally, students' homework should forward to teaching assistants for correcting. Then, teaching assistants reply a electronic mail with correction of students' homework to students. Finally, students should send back the refined homework to teaching assistants. However, mail list does not enforce that kind of learning flow. The prime causes of the problem become evident when using Web to improve the discussion style of mail list. Many network tools on Web, for instance hypermail[1], can arrange mail in a more constructed style. Although Web can implement some learning techniques, for instance the guided tour for courseware [Hauck, 1996], and footsteps for a quiz activity [Nicol *et al.*, 1995] so on, these learning techniques arose a common problem — learning flow beyond control. Johnson (1996) used state to resolve the problem, but it did not show how to resolve it on Web. (3)*Lack of behavioral records for promoting learning efficiency.* Web can server as an excellent media of group learning for distant, statistic, and asynchronous communication. However, the information is not enough for an instructor to figure out the relationship between students' behavior and learning performance. Many educators think that learners' behavior records, called *portfolio*, is very important for assessing learning performance [Paulson, 1991; VanLeirsburg, 1990]. However, existing distance learning systems do not have a tool for instructors to create the portfolio of every learner. As distance learning has become more prevalent on Web, attention has been given to manage users' behavior in distance learning. Albatross [Yeh *et al.*, 1996] uses synchronous navigation control to avoid learner-centric phenomenon. In other words, learners are free and active in their learning process, while instructors can not put constraints to learners' behavior. Some techniques can partially promote learners' learning efficiency, for instance guided tours, path mechanism [Zellweger, 1989], footsteps, etc. However, those techniques require records of learners' behavior.

To sum up, a distance learning environment wholly depends on Web will lack some essential elements of group learning to satisfy users' requirements, for instance learning activity, learning flow, portfolio etc. For instance, the temporal issue must be considered to construct a quiz activity. Then an instructor can specify the beginning time and duration of a quiz activity. Additionally, a teacher should be able to efficiently find out students' answers of specific questions in a quiz activity. Consequently, the designing model must embed the fundamental mechanisms, including learning activity construction, learning flow definition, and portfolio management, to precisely satisfy an instructor's requirements for designing a distance learning environment on Web.

Motivating Example

Here is a motivating example to depict how the system operates for designing a distance learning environment. The scenario of the motivating example describes a quiz activity followed with discussion activities. [Fig. 1] illustrates following narration of the scenario.

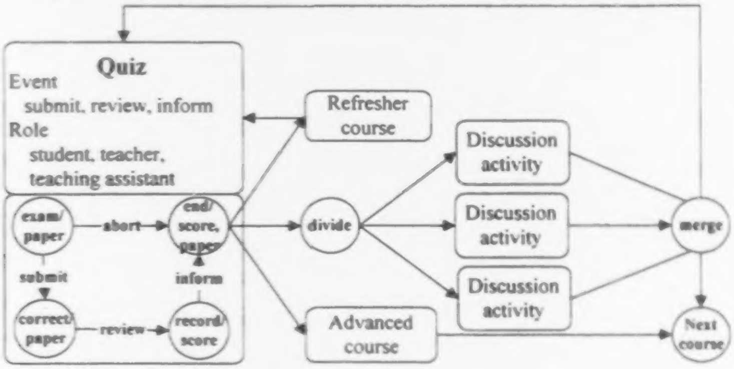

Figure 1: The motivating example.

(1)*Constructing the quiz activity*: For instance, an instructor should define roles and events of an activity. The roles involved by the quiz activity include teacher, teaching assistant, and student. The events triggered by the quiz activity include submitting an assignment, reviewing the corrected paper, informing a student, aborting the quiz. (2)*Defining learning flow*: Both learning flow in the quiz activity and learning flow among activities must be defined. In the scenario, the learning flow in the quiz activity includes four states, that are exam, correct, record and end. [Fig. 1] illustrates transition mechanism of the four states and output of each state. Furthermore, the following activity of the quiz activity is assigned by one of the subsequent activities, that is refresher course, discussion activity, and advanced course, according learners' score of the quiz activity. (3)*Querying learners' behavior*: First, an instructor can observe the learners' behavior in an activity. For instance, an instructor may want to figure out the relationship between score and duration of the exam state in the quiz activity. Second, learning flow will implicitly imply learners' learning style. An instructor may want to figure out learners' learning style from the learning flow in and among learning activities. For instance, an instructor may in interested in "did a learner abort a quiz?", "how does a learner join the advanced course?".

Construct Learning Activities

An *activity* is composed of a set of *events*, a set of *triggers*, and a set of *roles*. For example, an instructor may arrange a discussion activity. The activity has three roles involved: teacher, moderator, and students. The teacher assigns a topic for discussion. The students can submit opinions of the topic to the moderator. The event of submitting opinions defined a procedure to store opinions into data repository. Other students, moderator, or even teacher may reply an opinion. The system should notify the moderator to make arrangement of the opinion if an opinion does not be replied more than two days. In the above mentioned activity, teacher, moderator, and students are *roles*. Assigning topic, reading opinions, and submitting opinions are *events*. Automatic notification is a (temporal) *trigger*.

To define an event, a user should define the following items of an event: (1) notice, (2) form, (3) transition mechanism, and (4) temporal constraint. The notice part contains the advice of this event. For example, the notice item indicates the valid duration of the submitting event in a quiz activity. The form part describes the information required to be submitted back. For example, the submitted paper for a quiz activity should contain the name of the student, the ID of questions, and the answers. The transition mechanism describes how the event changes learning state in an activity. The temporal constraint part defines when to complete the event.

A trigger is used to initiate events. For example, the trigger of submitting paper event will initiate the defined procedure of the event to store the submitted papers. A trigger should define the conditions to initiate an event. The types of the condition to initiate an event include data exchange, role constraints, and temporal restriction. The trigger of data exchange type was used in database systems [Gehani & Jagadish, 1991]. Because Web can easily integrate with databases, triggers of an activity are consequently feasible by database.

A user table is required to describe all the information of the users and all the default roles of the users in an activity. For each activity, a particular role may be assigned to a user. Sometimes, we also define groups for an activity and assign a user in a group a particular role. For example, a teacher may want to divide a C++ homework into four tasks: problem analysis, object definition, object implementation, and object integration for the answer of a problem. Each task is done only by a particular role. Thereafter, we form groups from the students and assign a role for a student of each group to do the particular task.

A finite state machine can represent the *learning states* of a learning activity. A finite state machine is composed by states and transition mechanism. A state is represented by a fill-out form on Web. Users can only access the fill-out form through the transition mechanism. The transition mechanism is composed by CGI programs of the fill-out forms. The CGI programs will cause the transition from one state to another. The *portfolio* of a learning activity is composed with output of a learning state with time stamps, logs of events with time stamps, and users' duration of a state. In other words, users' inputs on a state by the fill-out form are attached with a time stamp as portfolio. Although the portfolio is a mine of pedagogical meanings, it is difficult for a teacher to figure out the pedagogical meaning from the portfolio. Consequently, portfolios are stored into a database so that one can easily query requiring portfolio. [Fig. 2] illustrates the interface to construct learning activities. The upper left corner of [Fig. 2] let an instructor to manage the learning state by adding, deleting, editing and finding a state. The upper right corner of [Fig. 2] manages the trigger of the activity. The bottom event of [Fig. 2] defines the event, transition mechanism and temporal constraints. The group and role of the interaction part is control by Web server. Consequently, only the right users can access the right pages.

Figure 2: The interface for designing learning activities.

Define Learning Flow

To scaffold learners, an instructor must guide learners' learning flow among learning activities. Users have mutual obligation to accomplish a task after a distance learning environment can construct a learning activity. For instance, a teacher must prepare problems of a quiz, define the duration of a quiz, and arrange a proper chance to hold a quiz. A student must study the course of a quiz, participate a quiz with temporal pressure, and submit paper of a quiz to teaching assistants. Although learning activities can increase learners' participation, they can not guide learners with a sequence of learning activities. In other words, a distance learning system should guide learners not only in activity, but also among activities. For instance, a refresher course should tag after a quiz activity if the score of a student is low. A discussion activity should tag after a quiz activity to figure out students' misconception. Learning flow among activities can bind various learning activities in a distance learning environment.

The relationships among learning activities must be defined so that users can always learn with a suitable role. However, using finite state machine to represent the learning flow is not sufficient to reserve the concurrent sequence among learning activities. For instance, many discussion activities are going after a quiz activity. Consequently, the following operators are used to represent requiring learning flow among learning activities: (1)*Linear learning*. Linear learning means that a subsequent learning activity follows a prior learning activity. The SEQUENTIAL operator can define the basic sequence of learning flow. For instance, students can join the next course after finishing the advanced course. This situation can be defined as "advanced course SEQUENTIAL next course." (2)*Branching learning*. Branching learning means to activate the demanding subsequent learning activities according portfolios of a prior learning activity. There are two kinds of branching learning operators: AND-Split operator and OR-Split operator. The AND-Split operator indicates that the subsequent learning activities are synchronous activated. For instance, students participate different discussion activities after a quiz activity in the scenario of motivating example. The upper part of [Fig. 3] represents the scenario as "divide AND-Split group1 discussion", "divide AND-Split group2 discussion", and "divide AND-Split group3 discussion". The lower part of [Fig. 3] shows the learning flow in a graphic style. The OR-Split operator indicates that only one subsequent learning activity is activated by evaluating the portfolio of the prior learning activity according to the condition of branching. For instance, either advanced course, discussion activity, or refresher course are selected as the subsequent activity according score of a quiz activity. (3)*Learning coordination*. Learning coordination defines how learners coordinate with each other after branching learning. Join operators are used to represent the conditions of learning coordination. Join operator indicates that many prior learning activities coordinate for a subsequent learning activity by evaluating the portfolio of prior learning activities. Sometimes the outcome or the result of coordinated activities is dependent. This AND-Join operator can define the condition, that the subsequent learning activity is activated only after all the prior learning activities are finished. OR-Join can define the racing situation of many learning activities. In other words, any prior learning activities can activate the subsequent learning activity when any prior learning activities have finished. (4)*Iteration*.

BEST COPY AVAILABLE

The operator defines the iteration of learning flow. For instance, unqualified students will iterate refresher course and quiz activity. The iteration of learning flow differs from repeating practice in CAL because the iteration of learning flow will activate a learning activity with students' portfolio. Consequently, the content of a learning activity will change with students' portfolio.

Figure 3: The interface for learning flow definition.

Portfolio Management

Learning activities accumulate a large amount of portfolios. Retrieving the meaningful information from the portfolios is difficult for an instructor without an effective query method. However, comprehending learners' behavior from the portfolios is very important in a distance learning environment. Using hypertext to navigate for specific data is not a suitable method to query specific data, for instance structural data, temporal data, etc.. Furthermore some educators [Arter & Spandel, 1992] recommended that a portfolio assessment must be carefully designed. Consequently, we do not propose a method to assess students' portfolio. Instead we propose tools for an instructor to retrieve meaningful information from learners' portfolios.

Learning flow endows the portfolios additional meanings, for instance temporal data, sequential order, social interaction. Traditional query language, such as SQL, can not effectively query those data. In our model, there are three cues to observe learners' specific behavior, including portfolio, learning flow, and event trace. An instructor can mine useful information about learners' behavior from the following queries. (1)*Portfolio query*. Students' specific behavior must be represented as proper style to query it from a large amount of portfolio. After using finite state machine to represent the learning flow of a learning activity, an instructor can easily retrieve learners' specific behavior from the portfolio by the learning flow expression. The notation of the expression is "SELECT output FROM state IN activity WHERE condition." For instance, one can query the corrected paper of the quiz activity by the pattern "SELECT papers FROM correct IN quiz WHERE user's name=chen." The left upper corner of [Fig. 4] illustrates the portfolio query. Note that a quiz activity may follow many different courses so that a learner's portfolio of a quiz activity would accumulate with time. The temporal condition in the WHERE clause enables instructors to figure out learners' temporal change in portfolio. (2)*Learning flow query*. In contrast to the learner-centric management in portfolio query, learning flow query provides an activity-centric method to figure out learners' behavior. Instructors usually need to find out the learners with some specific learning activities flow structure, that is "activity1, activity2, activity3, ...". For instance, a teacher may want to list the students with the following learning history: 1. Join a quiz activity, 2. Join a refresher course, 3. Join a quiz activity, 4. Join an advanced course. The right part of [Fig. 4] shows the result of the learning flow query in the left second row of [Fig. 4]. (3)*Event trace query*. Event trace indicates how a user's state changes from one state to another state. Event trace is important for an instructor to understand a learner's learning style. For instance, a teacher may want to query how the learning state changes from the correct state in a quiz activity to the scaffold state in a refresher course. The query result can indicate a learner's learning degree of reflection by the time interval between submit a paper and start a refresher course before informing about score. A learner's degree of reflection may be high if the event trace is the form "submit - abort -...- inform ...".

Conclusion

To promote learning efficiency of a distance learning environment, first we depict the requirements to managing the learning flow and portfolio of a distance learning environment on Web. To satisfy the requirement, an ideal model for designing distance learning must be able to construct learning activities, define learning flow, and query specific behavior. We proposed a designing environment that an instructor can use a friendly interface on Web to construct learning activities, define learning flow, and query specific behavior. We use a motivating example to depict how the model operates with available technologies. Consequently an instructor, who developed distance learning on Web, can benefit their learning environment from the designing methodology without additional burden. Most important advantages of the model, that is managing learning flow and portfolio, enable an instructor to precisely observer learners' interaction in a distance learning environment on Web. We showed that available technologies can support the designing model for an instructor to design and implement the learning environment for better learning performance.

Awareness and Virtual Cooperative Interaction in the Learning Web

Lee Li-Jen Chen and Brian R. Gaines
Knowledge Science Institute, The University of Calgary, Alberta, Canada T2N-1N4
{lchen | gaines}@cpsc.ucalgary.ca   http://ksi.cpsc.ucalgary.ca/KSI/

ABSTRACT The article investigates *awareness* issues involved in the learning web. It presents a conceptual model for *virtual cooperative interaction* and examines how one would ensure the continual participation and contribution by information providers to the web. For example, a virtual art gallery on the web has an *intensional expectation* of its potential audience: guest artists often contribute in order to gain recognition from peers; and its webmaster can gain satisfactions via receiving popular site awards (e.g., "the best website for cubism"). The example involves social psychological processes which instigate and maintain *virtual cooperation*. These processes can be analyzed by the motivational and reinforcement aspects of the conceptual model. These phenomena are common in existing activities such as those of scientific research communities and those of emerging learning communities on the Internet.

1. INTRODUCTION

The 1990s have seen the emergence of large scale collaborative activities on the Internet using email, list servers, news groups and the World Wide Web. There have also been developments of systems using some of these technologies to support smaller closely-coupled collaborative learning groups. In terms of the standard time/space taxonomy for CSCW (computer-supported cooperative work), these uses of the Internet are generally virtual in space and range from highly synchronous to highly asynchronous interactions. However, many of the major applications of the Internet raise new issues that are not adequately addressed by existing models and taxonomies of CSCW. Small groups of individuals working together generally have well-defined roles and mutual awareness of roles, tasks and activities. However on a list server, a discussion may be initiated with only a vague concept of other potential participants but with strong expectations that a collaborative activity will result. On the World Wide Web material may be published without only a vague conception of potential users yet that material may play an essential role in a collaborative active in some community, possibility not involving the originator, and perhaps a community of which the originator is not part.

The web was originally conceived and developed at CERN for the purpose of assisting and facilitating collaborative interactions among high energy physicists, working at various institutions in different countries, to conduct joint research projects. Since 1993, it has diffused at a phenomenal rate and gradually has subsumed various popular Internet services such as: USENET news group, electronic mail, etc. The original charter of the web is summarized in the following quote: *The World Wide Web was developed to be* ***a pool of human knowledge****, which would allow collaborators in remote sites to share their ideas and all aspects of a common project* [Berners94].

The notion of the **learning web** was presented at EdMedia '95 as: *a systemic approach to the modeling and support of knowledge processes in a learning society* [Norrie95]. This paper develops a model of virtual cooperative interaction and the support of awareness in the learning web. In carrying out cooperative learning, learners use a variety of tools. The proliferation of **computer mediated environments** (CMEs, e.g., conferencing systems, shared media space) allows learners to utilize the new resources for their cooperative interactions. CSCW or groupware systems are often classified as supporting either synchronous or asynchronous cooperative interactions; but this simple distinction fails to capture the complexity of large scale collaborative work. Typical groupware supports cooperative interactions ranging from small closely coupled team numbering 2-5 people (e.g., co-authoring systems [Neuwirth94]) to large group of participants numbering 50-100 (e.g., electronic meeting systems [Dennis90]). However there is now an emergence of *large scale groupware* on the Internet and World Wide Web, with participants numbering in hundreds or thousands.

2. THE LEARNING WEB AS SOCIOWARE

The diffuse collaborative communities that have formed on the Internet suggest the need to reconsider existing notions of CSCW. Large scale groupware differs not only in the quantity, but also in the quality of cooperative interaction. The fundamental nature of interaction on the web can be characterized as **virtual cooperative interaction**. The word "virtual" has two senses here: first, it denotes the notion of *virtual space*, i.e., the cooperative interaction occurs in a non-physical space which allows participants to be situated in geographically separate locations; second, it denotes that the *intention* to engage in cooperative interaction itself may not necessary pre-exist or be conscious. Traditional notions of groupware focus on the first sense (tele-presence in virtual space), but there is a need to extend the notion of cooperative interaction to encompass the latter sense of virtual cooperative interaction also.

Frequently, information resource contribution and exchange on the web involve cooperative interaction without pre-planned coordination. In fact, participants on the web may have no intention to cooperate in the first place. Quite often, a resource provider and a resource user are unaware of each other's existence until their first interaction. Nevertheless, the interactive process between them is still loosely cooperative in nature. It is an unusual form of cooperation where a resource provider might never know the identity of her resource users, nevertheless still continues to contribute anyway. It differs from the traditional team-oriented cooperation where group tasks, goals, and purposes are usually well-defined. What does she gain in return in such a seemingly one-way cooperative interaction? Is it simply an expression of altruism? What are some possible motivations for her to contribute to the web? In general, how would one ensure the continual contribution of an information provider? These questions can be answered more clearly in the context of *socioware*.

The present paper defines **socioware** as: *computer-mediated environments for supporting community-wide processes which expedite virtual cooperative interactions*. Information inquiry and response, dissemination of ideas, and social networking are examples of functionality of the learning web [Norrie95]. In essence, the goal of socioware is to facilitate emergent pro-social behaviors for self-organized, virtual collaborative communities. This paper models the Internet as a whole (the web/net) as large scale socioware supporting cooperative interactions which differ qualitatively from goal directed, highly coordinated team-oriented collaborations supported by conventional groupware.

3. CONCEPTUAL MODEL OF THE LEARNING WEB

This section describes a detailed learning web model that encompasses collaborative activities supported by traditional groupware and by emergent socioware. The model analyzes the following five basic elements for the learning web in terms of virtual cooperative interaction:

1. *discourse patterns*
2. *time-dimension of virtual interactions*
3. *awareness hierarchy*
4. *motivations for cooperative behaviors*
5. *emergence and maintenance of virtual cooperative interaction*

Together they present three aspects (what, why, and how) of the conceptual model: (i) the descriptive aspect comprised of the first three elements which characterize and classify virtual cooperative interactions; (ii) the prescriptive aspect that provide motivational reasons for individuals to participate in virtual cooperative interactions; and (iii) the operational aspect of how virtual cooperative interactions initiate and function.

3.1 Discourse in Virtual Cooperative Interaction

Communication is an essential element of cooperative interaction. Generally speaking, there are two types of communications on the Internet, namely: *discourse* and *publication*. This subsection proposes a temporal punctuated-discourse model of virtual cooperative interaction which models both modes in an integrated way.

3.1.1 A Punctuated Discourse Model

A conventional taxonomy of Internet might describe its services in terms of their utility, but it does not provide an integrative model of the way in which they support communities. Such a model can be developed by noting that what distinguishes discourse from publication is that in discourse it is expected that the recipient responds to the originator, whereas publication is generally a one-way communication. However, on list servers some material is published in that the originator expects no specific response, and material published in electronic journals or archives often evokes a response. The following diagrams show the different characteristics of the main Internet services in terms of these issues.

Figure 1 shows email discourse as a cycle of origination and response between a pair of participants communicating through a computer-mediated channel. Figure 2 extends Figure 1 to show list server discourse as a cycle of origination and response between participants that is shared with a community through a computer-mediated channel. The community involvement leads to more complex discourse patterns in that: the originator may not direct the message to a particular recipient; there may be multiple responses to a message; and the response from the recipient may itself trigger responses from others who did not originate the discourse. For a particular discourse sequence this leads to a natural division of the community into active participants who respond and passive participants who do not.

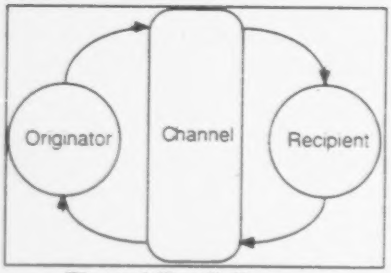

Figure 1 Email discourse

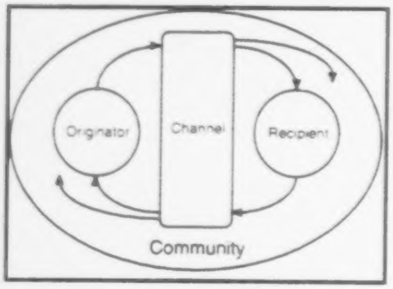

Figure 2 List server Discourse

Figure 3 modifies Figure 2 to show web publication as an activity in which the channel is buffered to act as a store also. The material published is available to a community and the originator is unlikely to target it on a particular recipient. Recipients are not expected to respond direct to the originator, but responses may occur through email, list servers or through the publication of material linked to the original. Because the published material is not automatically distributed to a list, recipients have to actively search for and discover the material. The common structure adopted for the diagrams is intended to draw attention to the commonalties between the services. List server discourse is usually archived and often converted to Hypermedia on the web. Web publications do trigger responses through other services or through links on the web. A search on the web may not discover a specific item but rather a related item on a news group, list or by an author, and result in an request for information to the news group, list or author. Individuals and communities use many of the available services in an integrated way to support their learning processes. Figure 4 subsumes Figure 1 through Figure 3 to provide an integrated model of the learning web on the Internet that captures all the issues discussed. It introduces two major dimensions of analysis: the *times* for each step in a discourse cycle; and the *awareness* by originators of recipients and vice versa.

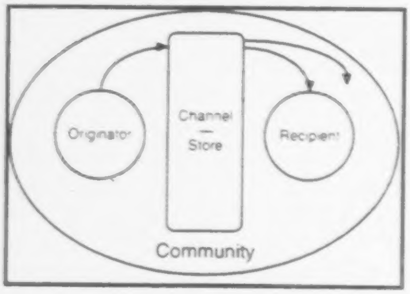

Figure 3 World Wide Web Publication

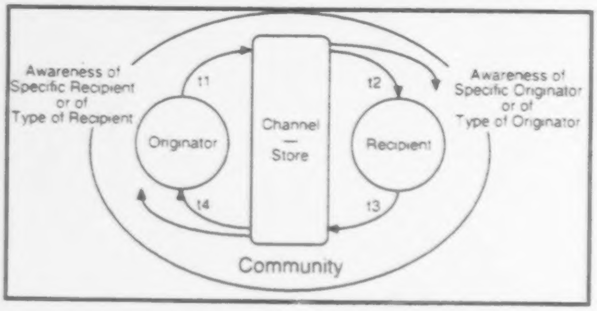

Figure 4 Punctuated Discourse

3.1.2 Time-Cycle of Punctuated Discourse

The four times shown in Figure 4 are:

- t1: the origination time— the time from a concept to its expression and availability
- t2: the discovery time— the time from availability to receipt
- t3: the response time— the time from receipt to expression and availability of a response
- t4: the response discovery time— the time from response availability to receipt

Note that individual's cognitive processing times and channel delays have been lumped. A study focusing on the impact of communication delays would want to consider them separately, otherwise there is no significant distinction. A general principle might be that communication delays should not be greater than individual's cognitive processing times. Note also that the diagram is to a large extent symmetrical— the recipient becomes an originator when responding.

An important overall parameter is the round-trip discourse time, t1+t2+t3+t4. The **time-cycle** of virtual cooperative interaction is defined by averaging the round-trips of discourse times. If this is small, a few seconds or less, we talk in terms of synchronous communication. If it is large, a few hours or more, we talk in terms of asynchronous communication. If it is infinite, so that there is no response, we talk in terms of publication. However, this analysis shows that there is a continuous spectrum from synchronous through asynchronous to publication. The discovery times, t2 and t4, are very significant to publication-mode discourse, and attempts to reduce them have lead to a wide range of *awareness-support tools* that aid potential recipients to discover relevant material and originators to make material easier to discover [Gaines96, Chen96].

3.2 The Time Dimension in The Learning Web

When two or more individuals participate in the learning web, they often take on dual roles of originator and recipient in punctuated discourse. Gradually they become locked into *social entrainment processes* [McGrath90]. Computer-mediated environments, such as news groups and shared drawing systems, provide specific external signals which set the pace of virtual cooperative interactions for participants. For example, the average *time-cycle* for posting to a news group and receiving a feedback is about one to few days. Whereas the partial time-cycle (t1+t2) for moving a mouse cursor in a real-time shared drawing system is around one to ten seconds. *External entrainment* [McGrath90] occurs when the *actual* time-cycle of a virtual interaction fall into the range of the *expected* time-cycle anticipated by individual participants. When there is a wide discrepancy between the expected and the actual time-cycle of interaction, participants often feel frustrated and decrease their desire to interact. For example, if cursor movements in a shared drawing system begin to take more than a few seconds to complete, the participants will tend to stop their interaction.

Continuation of virtual cooperative interaction can also break down when *mutual* and *external* entrainment processes are not synchronized with one another [McGrath90]. When co-reviewing a book, the natural time-cycle for mutual entrainment is in days and weeks, since it often take that a mount of time to read a book and absorb the material properly. It is unlikely that co-reviewers will want to use IRC (Internet Relay Chat) to disseminate and exchange their reviews. Such a fast time-cycle of interaction is not well suited for activities involving deep, reflective cognitive processes.

Figure 5 Time Dimension of Virtual Cooperative Interaction

The time-cycle in the learning web often varies according to cognitive processes involved in any given moment of an activity. For example, during a collaborative writing session [Neuwirth94]: when co-authors' focus is on correcting sentences or paragraphs, the time-cycle involved is usually around few minutes; and when they focus on reviewing chapters, the time-cycle involved shifts to hours. Therefore co-authoring systems are classified in the range of time-cycles from second to day, in addition to be extensional oriented. The time dimension diagram of virtual cooperative interactions allows us to visualize CMEs in terms of an *interaction area* they encompass as shown in Figure 5.

Many groupware systems have been designed to support collaborative teams in which interactions are between known group members. In contrast, interactions in USENET news groups involve both extensional and intensional awareness of targeted audience. For example, one can respond to a question from a specific individual (an extensional oriented interaction) but do so publicly with the intention to address others who may have a similar question in mind (intensional oriented interaction). The relationship between the time-cycle and the relative strength of *extensional/intensional awareness* in the learning web can be illustrated in a time-dimension diagram (Figure 5). If the time-cycle is relative short, say in few seconds or minutes, we have an interaction that can be characterized as synchronous (real-time). If it is longer, we have interaction that is often described as asynchronous (delay-time).

No awareness of resources or providers, or only weak intensional awareness of types of resources and providers.

Figure 6 Communities Distinguished by Awareness

The key notion here is that the types of virtual cooperative interactions are differentiated on a temporal continuum rather than by discrete categories.

3.3 Awareness Hierarchy of Virtual Cooperative Interactions

At least three types of virtual cooperative community need to be distinguished. A **team** can be treated from a *collective stance* [Gaines94] as a single psychological individual that behaves as a compound role generated by the distributed activities of roles in a number of people. Each resource provider in a team has an *extensional awareness* of their actual resource users, and each resource user has an extensional awareness of the resource and who will provide it. In the tightly-coupled team, each person is usually aware of who will provide a particular resource and often of when they will provide it. In logical terms, this can be termed **extensional awareness** because the specific resource and provider are known, as contrasted to **intensional awareness** in which only the characteristics of suitable resources or providers are known. Both types of awareness are important in the awareness hierarchy of virtual cooperative interactions [Gaines96].

In a **special interest community** resource providers usually do not have such extensional awareness of the resource users, and, if they do, can be regarded as forming teams operating within the community. Instead, resource providers usually have an *intensional awareness* of the resource users in terms of their characteristics as types of user within the community. Resource users in a special interest community may have an extensional awareness of particular resources or resource providers, or an intensional awareness of the types of resource provider likely to provide the resources they require. This asymmetry between providers and users characterizes a special interest community and also leads to differentiation of the community in terms of core members of whom many users are extensionally aware, and sub-communities specializing in particular forms of resource [Gaines96].

In the **community of users at large**, there is little awareness of particular resources or providers and only a general awareness of the rich set of resources is available. Awareness of the characteristics of resources and providers is vague, corresponding to *weak intensional awareness*. These distinctions lead to human factors consequences in terms of the appropriate awareness mechanisms that need to be established for the learning web to function. In a team, resources may be identified precisely by location and name. In a special-interest community, resources may be identified by an intensional indexing scheme that classifies them in terms of the distinctions made by that community. In the community of users at large, resources may be identified both by indexing their content type using a wide variety of taxonomies and by indexing their actual content. These distinctions are summarized in Figure 6.

3.4 Motivations for Participation in the Learning Web

When many individuals participate in a multitude of punctuated discourses (Figure 4), a chain reaction occurs. The accumulative effect generated by this chain of inquiry-response-reaction-response-reaction (and so on) is an evolving topical thread that can become a part of *shared knowledge* among community members. Through automatic archival services such as Hypermail or some individual efforts such as FAQs (Frequently Asked Questioned) and webpages, the shared knowledge persists and grows. An interesting question is: why should individuals contribute to this pro-social process?

Generally, interpersonal behavior can be characterized as a *social exchange* between people, and these social exchanges typically involved both rewards and costs to participants. On balance, an individual will perform those actions which produce the greatest rewards at the least cost [Shaver87]. Therefore according to this cost-benefit calculus, a perceived potential for rewards must exist for individuals to participate and contribute in a cooperative relationship. In contrast with classical social exchange theories [Cook87] (e.g., Kelly and Thibaut's interactional matrix model [Kelly78]) which emphasize dyadic interactions between individuals, **collective social exchange theory** focuses on interactions between individuals and their community. Conceptually, the Internet community is viewed from a *collective stance* [Gaines94] as an entity to 'whom' individual participants exchange information resource with. This collective entity offers participants a valuable informational service (namely, as *a pool of human knowledge* [Berners94]) in exchange for their contributions.

The *norm of reciprocity* is fundamental to social exchange and leads to contributing behavior. The reciprocity norm creates an obligation for repayment that must be satisfied if the interaction is to continue [Shaver87]. However, the way reciprocity operates in collective social exchange is more subtle than in conventional social exchange between individuals. Why should one reciprocate (through contribution) in a situation where social responsibility is relatively *diffused* among community members? One motivation for contributing to the net is for individual to gain positive *self-image* [Jones82]. In this case, an individual has internalized the norm of reciprocity and acts according to the principle of **equity theory**: that is, a person will seek to maintain his ratio of rewards to costs as the same as that of relevant comparison persons [Walster78]. A sense of *guilt* would occur if the individual perceives he has not contributed enough to the community. Hence, he would want to reciprocate fairly.

Another more subtle motivation is that of contribution as an investment in **social power**, that is, the *capacity* of a person or group to affect the behavior of another person or group [Schopler65]. Contributions made by an individual may not only help others but may also help her to gain name recognition from peers. The more one contributes publicly and receives recognition for one's contributions, the more one gains the capacity of power to influence others or the community as a whole. The added weight in recognizing who is first to contribute relevant information also motivates individuals to volunteer information resource more readily. The competition for priority in contribution has been well documented in Merton's studies on the reward system in scientific discovery [Merton73].

The motivational dimension illustrates the importance of *feedback loops* [Losada90] in the reinforcement of virtual cooperative interaction. It provides a coherent explanation for the apparent altruistic behavior of information providers on the web.

3.5 Reinforcement of Virtual Cooperative Interactions

Possible motivations for providing information resource on the web are gaining positive self-image and name recognition. But how does a pro-social behavior initiate and continue? The concern here is with the relationship between the *effect* of an individual's behavior in a *virtual cooperative community* and its impact on the individual's later behavior. This is the basis to **operant conditioning**, the learning process by which behavior is modified by it the consequences of previous similar behavior [Ritzer92]. An individual emits some behavior. The community in which the behavior occurs in tern "acts" back in various ways. The reaction—positive, negative, or neutral— affects the individual's later behavior.

Social learning theory suggests that novel social behavior is first learned through imitation of actions taken by others who act as (social) models [Bandura63]. The reinforcement received by a model serves as information to the person about which behaviors are acceptable and appropriate for the circumstances. Once a novel action has been acquired through imitation, its probability of continuation is depended on the reinforcement it receives. *Vicarious reinforcement*, as well as direct reward or punishment, can play a part in social learning [Shaver87].

On the web, an individual's first successful encounter with a homepage full of relevant information resource provides a positive role model for imitation. Her subsequent positive net-surfing experience will further increase her exposure to other positive models. Once an individual internalizes the web culture which encourages construction of personal homepage (which coincidentally also provides virtual persona for self-image), she will come to view that contribution to the web as a pro-social behavior and act accordingly. The dynamic of *social exchange* then comes into play here, if the costs of putting up information resources (e.g., research papers, hyperlinks to relevant webpages) are relatively low to her (e.g., she has necessary skills and resources), she would contribute to the web. In addition, an original intention to contribute to the web community does not need to exist, she may use her homepage to organize her knowledge resource and contribute to the web community as an after thought (or as a by-product). In this situation, the extensional audience is herself together with a vague sense of intensional awareness of other potential resource users. This form of contribution in punctuated discourse is depicted in Figure 3.

How does reinforcement come into the picture? Frequently, one would encounter some homepages that had been constructed months or years ago without any revisions or new contributions. Their authors have neglected them and ceased to contribute. Once a novel behavior has been acquired, it needs to have *intermittent, positive reinforcements* to sustain the behavior [Bandura63]. In order for reinforcement to take place, there must exist a feedback loop like the one depicted in Figure 4. The round-trip cycle (t1+t2+t3+t4) of virtual cooperative interaction provides an individual the necessary awareness of the *effectiveness of investment in social power* which is crucial to reinforcing the behavior and leading to similar future actions.

An observable measurement of the effectiveness of social power on the web is the relative popularity of a website. The popularity of a homepage can be inferred from recognition earned by its visitor frequency counter, commentaries in its public guest-book, awards given by reviewers of popular websites, and the number of other webpages linked to the page, etc. These gauges of popularity (which measure the relative power for social influence) provide direct reinforcements (can be either positive or negative) to an information provider. They also offer indirect, vicarious reinforcements to other information providers by providing social models for comparisons.

4. SUMMARY AND CONCLUSION

The support of virtual collaborative interaction on the Internet has developed pragmatically without deep conceptual models. Awareness-support tools such as Yahoo and Lycos have been developed because of a perceived need to ameliorate information overload through better indexing tools. However, the indices generated by these tools also contribute to the social exchange mechanisms that motivate participation in Internet communities, and the design of such tools has to recognize their multiple roles.

	Groupware	**Socioware**
Awareness	strong mutual extensional	weak mutual intensional
Time-Cycle of Interaction	short to medium (seconds to days)	medium to long (days to years)
Motivation for Cooperation	individual social exchange	collective social exchange
Power Relations	well-defined roles as part of team definition	emergent roles from investment in social power capacity

Figure 7 Comparisons between Groupware and Socioware

The early development of the conceptual model described in this paper led to the authors' realization that *chronological awareness* was not well-supported by existing web tools [Chen96]. CHRONO[1] is a tool resulting from this analysis. We noted that one dimension of awareness management is keeping track of a site where relevant information has been available in the past. CHRONO generates a "what's new" page for a site automatically by indexing the site in reverse chronological order so that a visitor may readily note changes that have occurred since his or her last visit. *WebWatch* [Specter95], *Katipo* [Newberry95], and *URL-Minder* [NetMind95] are other chronological awareness tools that track changes in specified documents. The key question to ask in developing new awareness support tools is "what is the starting point for the person seeking information? i.e., the existing information that is the basis for the search" A support tool is then one that takes that existing information and uses it to present further information that is likely to be relevant. Such information may include relevant concepts, text, existing documents, people, sites, list servers, news groups, and so on.

The conceptual model presented in the article implies that for successful maintenance of continual virtual cooperative interactions in the learning web, the following criteria must exist:

- establishment of resource awareness for initial encounter
- establishment of mutual awareness as a feedback loop for continual virtual cooperative interactions
- compatibility between the expected and the actual time-cycles of virtual cooperative interactions
- properly situated expectation of fairness in terms of collective social exchange
- accumulation of positive feedback for reinforcements in virtual cooperative interactions

The current model can also be used to categorize computer-mediated environments roughly into groupware and socioware (Figure 7). It also identifies the types of systems that are needed to expedite collaborative activities. It focuses on participants' motivations and power relationship which determine their social roles, goals, expectations in the learning web.

The article contributes to CSCW research by drawing attention to their added significance in socioware like the web where social and organizational structures are fluid and less well-defined. The conceptual model for virtual cooperative interactions in the learning web expands the scope of groupware research. It provides a framework encompassing all forms of CSCW from teams through organizational workgroups to diffused, evolving communities. Modeling and supporting virtual cooperative interactions on the Internet are important new challenges for distributed learning research.

Abstract: Existing Computer Assisted Learning (CAL) systems use computer programs to simulate a teacher in individual learning. However, regardless of how good the CAL system is, a student can hopefully interact with learning companions and teachers. Owing to the popularity and easy access of the computer network and communication tools, network facilities can be incorporated into a CAL system and make it a Computer-Supported Collaborative Learning (CSCL) system. To attain a good learning result, a CSCL system must be able to (1) arrange a group learning model, (2) constraint and notify the students to learn according to the arranged model, and (3) have query facilities which provide the teacher with information regarding what a student has done and learned, and what a student should do. The rule based system that is conventionally used can not sufficiently provide those required functions. In this paper, we account for why and how to use an active database system can achieve those goals.

Introduction

Existing Computer Assisted Learning (CAL) systems use computer programs to simulate a teacher in individual learning. However, regardless of how good the CAL system is, a student can hopefully interact with learning companions and teachers. Owing to the popularity and easy access of the computer network and associated communication tools, network facilities can be incorporated into a CAL system and make it a CSCL system. Students in a CSCL system can learn by discussing, asking questions, or collaborating through the computer network. Wells (1992) summarizes feasible learning activities through conventional network tools for distance education. However, to achieve a good learning result, a teacher should carefully arrange the group learning activities and understand the status of students well.

Collaborative learning [Bricker *et al.*, 1995; Monaghan & Clement, 1995] styles are often used in a conventional classroom. The students can be divided into groups. The members of a group can be assigned with different roles. Tasks (homework or exercises) can be divided into different sub tasks that can be assigned to different roles in a group to tackle. Concepts can also be discussed from different perspectives. A role in a group should present his conception according to his/her assigned perspective. The learning effect can be improved because students can observe and learn things from different views. Besides, the students can be motivated through the group and peer pressure. The students in a group are more willing to cooperate, exchange ideas, and share experiences in order to get a good score for their group. However, it would be of great burden for the teachers to construct collaborative learning activities by existing communication tools, such as Internet Relay Chat (IRC), World Wide Web (WWW) and so on. The teacher should participate in the discussion and do the tasks for assigning roles, notifying students, enforce schedules, regulating students for what he/she should do, and accumulating information to understand the status of students.

The basic facilities for supporting a collaborative learning activity are regulations, agenda, and transcript. Most existing CSCL systems construct learning activities by using existing network tools. For instance, a teacher wanting to construct a collaborative learning activity on the computer network must implement the mechanism of regulation, agenda, and transcript on the computer network. Otherwise, the teacher should manually handle these tasks by himself/herself. Consequently, the difficulties encountered in constructing collaborative learning activities on current CSCL systems include the following.

First, a teacher has difficulty in constructing a collaborative learning activity because most network tools do not support collaborative style of working. The teacher must arrange the style of collaborative work and define what a group member can do. For instance, a teacher issues a homework that should be a collaborative task. This homework is divided into sub parts. Each part is assigned to a particular group member. Each group has a leader who should combine the four parts into a complete solution. For each part, the assigned member can present his idea and solution and other members can only provide suggestions and arguments. However, the group leader can modify the sub part solution. Group members can only view the results and discussion of their group, unless they hand out the results. These issues are referred to *specification and regulation* problem.

Second, a teacher must maintain the progress of an activity because network tools can not automate the agenda of an activity. Take the example in the above group homework. The teacher can define a schedule for each group, for each sub part, and the final results. Besides, if other members have an opinion regarding a subpart idea or solution, the assigned in charge member must respond in 24 hours. The issue is called *automating schedule* problem.

Third, a teacher wanting to query what is going on in collaborative learning activities must put tremendous effort into finding the required information in an amount of data generated. The historical data of a collaborative learning activity are called "complete *transcript* of the interactions" as [Davie, 1987] proposed. Consequently, a teacher will be bothered by the problem of information overloaded [Hiltz & Turoff, 1985] because he/she must monitor the progress of activities. Furthermore, a teacher can not dynamically prepare a course without the mechanism of querying the transcripts, which implies students' learning history. For instance, the teacher wanting to know the member who delays a group result. Another example is the teacher wanting to know the complete learning history of a student. We call this issue as *recording and querying transcript* problem.

This paper attempts not only to resolve the above mentioned problems of CSCL systems from a database perspective, but also to identify the required functionality for constructing collaborative learning activities of CSCL environment. The initial motivation of using a database system originates from considering the *transcript recording and querying* problem. Survey of the database technology reveals that the active database may solve the *specification and regulation* and *automating agenda* problems. To resolve the *specification and regulation* problem, the active database [Kim, 1995] is applied to construct a collaborative learning activity, which is independent of employed network tools. To resolve the *automating agenda* problem, the agenda of an activity can be automated by integrating temporal issues and an active database. To resolve the *transcript recording and querying* problem, the query powers of the database can solve the problem of information overloaded and make it feasible to query the transcript of an activity. Herein, the advanced technology (active database) and theory (temporal logic) is employed to draft the infrastructure of CSCL systems. To account for the above mentioned problems, an example describes the tasks to be performed. Next, our methodology is described to address the issues. Applying the methodology can also construct other collaborative learning activities.

A Collaborative Homework Example

A motivating example is presented herein to elucidate the difficulties of constructing collaborative learning activities. The collaborative learning activity uses a discussion model called IBIS [Kunz & Rittel, 1970; Conklin & Begeman, 1989], that is *Issue Based Information System*. The IBIS model starts with an issue. Many positions are then proposed to resolve the issue. Many arguments are available, which may support or object to a position. A position may derive a new issue, which may generalize, specialize, or replace the previous issue. The IBIS model is effective in collaboratively resolving a designing problem.

We assume that a teacher would construct a collaborative homework activity by using IBIS model. The teacher wants students to decompose a homework into three components. Students are subsequently divided into three groups and each group is assigned to discuss one of three components with IBIS model. Moreover, there must be a moderator in each group to summarize a solution in time. A student can propose a position and defend for his/her group; however, he/she can only propose the argument for the other group. A discussion for combination is held with IBIS model finally. Sub solutions of three components must be refined if some problems are found in the discussion for combination. A final solution is summarized after the discussion for combination. [Fig. 1] shows the collaborative homework with IBIS model.

The teacher immediately faces some requirements. First, students must be divided into three groups and the teacher desires that each group has a user assigned as a moderator, who can determine whether to derive a new issue and summarize a solution in time. Defining legal behavior for a different user is necessary. Second, a

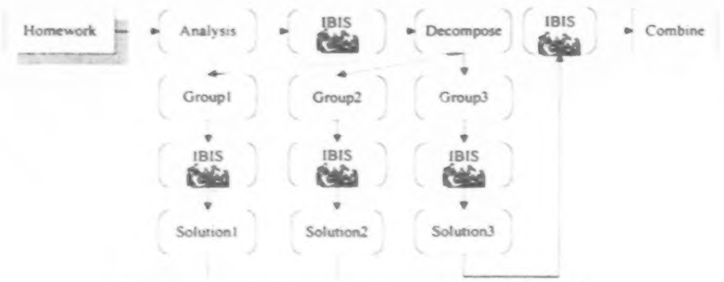

Figure 1: A collaborative homework with IBIS model.

moderator should notify the owner of a position to defend his/her position when other members argue the position. An active mechanism is required to automatically notify releasing the moderator's burden. Third, the teacher may want to identify the most argumentative position or the most active student from the records of discussion. A teacher requires an effective approach to query the transcript of an collaborative learning activity.

The following specifications illustrate how to construct the collaborative homework from a database perspective. To depict the enhancement, we used the informal representation: WHEN the <event> is detected and IF the <condition> is satisfied, THEN the corresponding <action> is performed. The events relevant for an activity include: database events (insertion, deletion, modification, retrieval), and temporal events (at a given time, or at any time after a specific event), such as "deadline of a homework." Conditions mean the expected results from a database query. Actions imply sequences of commands that can be database operation or external (user defined) processes, such as the notification.

Client

```
  Role: student
    Capability:
        propose a position to an issue in his/her group.
        propose an argument to a position in any group.
        request the moderator to derive a new issue.
        answer objects-to arguments of proposed position.
    Constraint:
        When requesting a teacher to derive a new issue from a position
                if the student did not propose a position
                then deny and notify the student "propose your position!"
  Role: moderator
    Capability:
        determine the initial issue.
        determine whether to derive a new issue.
    Constraint:
        When a student requests to derive a new issue from a position
                if the request is not answered currently
                then the request will be answered in the future eventually.
```

Role-based activity server

```
        check the identification, including group and role, of a client
        retrieve capabilities and constraints of the client from active database
        receive the action from active database to notify the client
  IBIS model
        When adding a new node
                then the type of node is one of {issue, position, argument}
        When creating a link
                then the type of link is one of {supports, objects-to, responds-to, questions is-
                  suggested-by, generalizes, specializes, replaces}
        When adding a child node to an issue
                if the type of link is responds-to
                then the type of the child node is position
        ...
```

Active notification:

When a question to a moderator for deriving a new issue is not answered
    if the question is not answered more than two days
    then immediately notify the moderator to make a decision.
When an objects-to argument of a position is not answered
    if the argument is not answered more than two days
    then notify the owner of the position to answer the argument.
...

Reasons for Applying an Active Database System to Distance CAL Systems

A large number of tools, e.g. Internet Relay Chat, World-Wide Web [Berners-Lee *et al.*, 1994], mail, on Internet provide various communication styles. The advantages come with those computer network communication tools including multimedia communication, asynchronous learning and discussion, on-line learning materials, social relationships, etc. Meanwhile, the flexible and distributive characteristics make some requirements of CSCL feasible on the computer network. Although those advantages could adhere to some requirements of CSCL, CSCL systems also involve some tasks that can not be implemented only by the network tools, e.g. controlling access to information repositories, scheduling, inferring, and notification. Integrating network tools with the advanced database technology can provide some required mechanisms that are difficult to be implemented merely by the network tools. For instance, the active database can satisfy the requirements of the collaborative homework example, including to define the regulation and agenda of an activity, to automatically handle the agenda of an activity, and to provide a mechanism for querying learning history.

- Constructing activity -- It refers to constructing the regulations of group interaction, among which includes the roles of users, their interrelationships, and notification. For instance,

  a moderator can derive a new issue and summarize a solution; students only propose positions in his/her own group; (1)
  system must construct the relationships of group. (2)

- Automating agenda -- Whether an interested event occurs and a response to it made must be monitored by a procedure automatically. For instance,

  the system should automatically notify a moderator who did not summarize a solution after the deadline. (3)

- Querying transcript -- A teacher can manage the activity through querying the transcript of an activity. For instance,

  list the students who often propose argument to other groups.

Most of the current CSCL environments did not consider how to construct a learning activity with the supports of a database. Consequently, aforementioned requirements, that can be easily achieved by a database, can still not be satisfied in the existing CSCL systems.

Active Database Support for Distance CAL Systems

An active database monitors situations of interest, and when they occur, triggers an appropriate response in a timely manner [Kim, 1995]. There are three components in an active database. First, an event monitoring subsystem monitors situations of interest. Second, a set of rules can be triggered by a series of events. Third, an execution model promises the temporal aspect of a response. Active database can satisfy the aforementioned requirements because an active database can attain aforementioned goals by the three components of an active database:

Constructing activity

Monitoring behaviors of a role is essential in a CSCL system. To effectively supervise users' behaviors, a CSCL system must construct users' interrelationships and attach constraints to communication behaviors.

- *Assign Role* includes specifying the capabilities and constraints of a user. In (1), users can be expressed as

  Teacher's capabilities: derive a new issue and summarize a solution (1a)
  Student's constraints: propose positions in his/her own group (1b)

- *Determine agenda* refers to the workflow of an activity. For instance, a moderator should make a summary after a conference activity. (2) can be refined as:

  Rule1 for moderator: summarize a solution when deadline is due (2a)

Automating agenda

This component includes two mechanisms: First, an active mechanism for checking conditions determines whether the event occurs. Second, a language specifies the responding procedure with temporal issues.

- *Detect event* -- Based on the determined agenda, an active mechanism monitors various events, e.g. the data access, and database update. The actions of an agenda specification will be triggered when an event satisfies the conditions of an agenda specification. In (3), it refers to

  System should automatically do something when Rule1 is triggered. (3a)

- *Activate action* -- An action specifies what to do when the event is triggered. The action specifications are associated with roles or activities. For instance, the specification in (3) is

  Notify the moderator to summarize a solution (3b)

Furthermore, an active database system is a superset of a traditional database system, that can naturally provide the power to query the transcript of an activity by query language, e.g., SQL. Most importantly, active database systems can provide functionality to support the requirements of a collaborative learning activity. First, active database systems can provide the *event-based interaction*, which servers as an inference engine matching the condition parts of agenda rules (2a). Second, an active database system can attach a role of some *collaborative constraints*, which maintain the relationships of users' roles. Third, the execution model can integrate learning activity *with temporal triggers*, which guarantee the workflow of an activity. To sum up, the approach integrates the model of active database with temporal issues. Consequently an end user, teacher, can construct a collaborative learning activity with a formal foundation.

Procedures for Using an Active Database in Distance CAL Systems

Some assumptions abound regarding the procedures for using an active database to construct collaborative learning activity in CSCL systems. First, the regulations of a collaborative learning activity are based upon the realistic assumption that users participating in a collaborative learning activity are not autonomous. Detecting whether a role's tasks were completed is subsequently necessary because of the assumption. Second, the collaborative learning activity must be accessible in a distance. Consequently, there must be a server that users can connect from any place. Third, users should be able to communicate and exchange data with the server. Consequently, there must be a user client program to interact with the user and communicate with the server. In other words, the collaborative learning activity consists of *clients, role-based activity server,* and *active database* on above assumptions.

The improvements originate from the server with the following enhancements. (1)*Identify the role of a client.* A client(user) can play many roles, and a set of clients(users) may only play a role. Identifying the role of a client is so important that the server can obtain capabilities and constraints associated with the role from active database. (2)*Endow capabilities of a role.* The capability of a client is defined according to its role in an activity. These capabilities originate from the previous specification of a role in the active database. The capabilities specify all the possible behavior of a role. (3)*Maintain constraints of a role.* The constraints of a role cover the capabilities with a temporal or non-temporal boundary of any particular role. Only under the satisfaction of these set of constraints can the client(user) undertake a given role. (4)*Autonomous notification to a role.* Notifying a role of some situations is useful for the server. The notification is made active by the specification of actions in active database. Autonomous notification is useful to maintain a long-duration activity because there is always someone forget to do something on schedule.

The collaborative homework example shows how to enhance the client-server architecture with roles and activity. Furthermore, that informal representation can be translate into the following formal syntax in an active database. A situation constraint, called *ECA rule* in the literature of active database, is defined as a sentence of the form:

define rule rule-name **on** <event> **if** <condition> **then** <action>

In these <...> items, *First-Order Temporal Logic* [Abadi & Manna, 1990] is applied to handle the temporal issues and specify the temporal constraints of an activity. FOTL has been introduced in the areas of information system design, and specification. Because the logical system used in above example is linear and discrete with respect to the model of time, only two future temporal operators of FOTL are required:

Nexttime A means "A is true in the next state" and A Until B means "A is true until B is true";

where A and B are formulas. Other temporal operators, such as Always, Eventually, can be expressed with the basic operators.

Now move towards the collaborative homework example. The first two rules for active notification must query the transcript of the IBIS discussion activity with a temporal issue. If the query results satisfy the expected conditions, the system will detect the temporal condition. When the temporal condition is satisfied, the action is triggered. To illustrate how to translate the informal representation into a formal syntax in an active database, the first active notification can be represented as the following ECA rules:

```
IBIS-Data(Node, Node_type, Date, Link, Link_type, ...)
define rule AutoNotifyTeacher
on (select IBIS_Data.Node
    from IBIS_Data
    where Node_type = ISSUE and
            Link_type = NULL)
if not(true Until (IBIS_Data.Date - Date > 2))
then notify teacher
```

Conclusion

In this paper, we have (1) analysed the requirements to construct collaborative learning activities for CSCL systems, (2) depicted why the active database can satisfy the requirements by a collaborative homework example, and (3) proposed the procedures for using an active database to construct collaborative learning activity in CSCL systems. Our results indicate the requirements to construct collaborative learning activity including constructing activity, automating agenda, and querying transcripts of an learning activity. The active database has distinctive advantages and additional facilities in contrast to other techniques for developing CSCL systems. We apply additional facilities, i.e. rule base, event monitor, and execution model, to the collaborative homework example and obtain the distinctive advantages, i.e. event-based interaction, defining regulation as rules, and temporal trigger. Furthermore, we indicate the requiring software architecture and procedures for implementation. The procedures demonstrate how the active database technology can be used to construct an activity and automatically execute the agenda of a collaborative learning activity in the required software architectures. Finally, we map the specification to the notion used in the discipline of active database to expound the feasibility of the methodology.

Most importantly, a perspective is provided herein that will benefit both CAL and Database communities. For the CAL communities, the proposed methodology for a CSCL system is based on considering the available database technology and requirements of CSCL systems. For the Database communities, new requirements can be realised, including the requiring functions, relationships among the functions, and interactions with users, when using a database to support CSCL systems. In the long-run, we believe that a synthesis of the disparate technologies will contribute to construct any CSCL system.

Abstract: We propose the *Global Learning Society* model of social learning. This model is based on the society structure in organizational behavior.. GLS model is composed of three layers: *Society Kernel*, *Learning Environment* and outside users. *Society Kernel* utilizes Society Server and Group Server to facilitate society management, such as user registration and login, user activity recording and activity server maintenance. *Learning Environment* provides users with various society learning activities, including individual and group learning activities. All these components are integrated through four communication protocols: user registration, group creation/deletion, member join/leave and data transfer. To prove the idea of the GLS model, we have implemented a demonstration system that runs on the Internet. This system uses state-of-the-art techniques of WWW (World-Wide Web).

1. Introduction

The use of computers has brought CAI (Computer-Assisted Instruction) technology into traditional education. The development of networking, especially Internet and WWW (World-Wide Web), opens a new era of *distance education*. Since 1980s, many scholars have made tremendous efforts to study new education strategies that utilizes computer networks. This includes cooperative or collaborative learning systems [Heh *et al.*, 1996], competitive learning system [Chan & Lai, 1995], reciprocal tutoring system [Chan *et al.*, 1996]. All these learning styles fall into one integrated framework called *social learning system*. [Chan, 1996]

A social learning system is defined as a learning system that runs on a computer network, where real users and computer simulated agents can work together. There are two categories of such systems: centralized social systems and distributed social systems. In *centralized social systems*, such as Integration-Kid [Chan, 1991] and People Power [Dillenbourg & Self, 1992], users connect to one specific computer and usually work with simulated agents. *Distributed social systems*, on the other hand, focus on the issue of supporting a group of persons, each in a different location. These persons learn together through networking.

One social learning structure, called SPOT (Structure, Protocols, Outcomes and Techniques), was proposed to explain the constitution of social learning systems. [Chan 1996] In SPOT, S (Structure) represents system configuration and agent types, P (Protocol) indicates the learning styles, such as collaboration and competition, O (Outcomes) is the learning effectiveness and evaluation, and T (Technique) includes related implementation techniques, such as dialog modeling and networking. The SPOT model describes almost all the components used in social learning systems. However, it is not well integrated.

From the viewpoint of sociology, a social learning system is a society built on computer network. Also, studies in organizational behavior [Robbins, 1983] suggests that members in a society participate in some specific group or individual activities and then present their group or personal behavior. As is the case with social learning systems, members (users or agents) in a learning society would be engaged in some group or individual learning activities to attain learning effectiveness. In terms of the SPOT model, a learning society introduces the society structure (S) and analyzes the learning activities (protocols) and its efficiency (O). The entire (virtual) society is built on the Internet (T), which makes the idea of a global learning society possible.

Following the SPOT model of social learning systems, we propose a *global learning society*, abbreviated as GLS. In Section 2, a three-layered architecture of GLS model: Society Kernel, Learning Environment and Outside Users, is described. This architecture is derived from the sociology structure in organizational behavior. Section 3 analyzes all the functions of components in GLS model and sets up the communication protocols among these components. Finally, this model is implemented on the Internet. The implementation makes use of state-of-the-art techniques of WWW (World-Wide Web) to prove the idea of GLS model in Section 4. Section 5 gives a conclusion.

2. Basic Model of Global Learning Society

A *global learning society* (GLS) is a virtual society built on the Internet. It allows the users to perform learning activities through networking. Users can participate in more than one society for different courses, and different societies can be set up for different courses in various ways. A GLS can be investigated from two perspectives:

- From the viewpoint of a system, users can take part in several learning activities, through which they interact with each other and the courseware. Meanwhile, these activities are managed by GLS, which provides an integrated Internet environment for such learning. Therefore, we have the following hierarchy: system, activities (with user interactions) and users.
- From the viewpoint of a society, a user chooses one activity to become a member of this activity. All users participating a specific activity naturally form a learning group. This matches the society structure in organizational behavior: society, group and member.

It is from these two perspectives that we develop the basic GLS model as a three-layered structure: Society Kernel, Learning Environment and Outside User (Figure 1). *Society Kernel* facilitates some centralized society management mechanisms, such as registration tool, user record and activity management, and group management. *Learning Environment* provides various social learning activities, including individual learning activities and group learning activities. These activities in the environment implement different computer-assisted learning methods for traditional education. As a result, users in different places can choose different learning styles in Learning Environment to meet their own needs.

Each user in the GLS model has a unique name. Users can be managers, teachers, students, guests, or just software agents, and are divided into three categories by their roles:

- System Manager: A system manager is one who is in charge of all system functions in the Society Kernel.
- General User: A general user can be a teacher, a student, or a guest, who carries out the designated learning activity in Learning Environment.
- Software Agents: A software agent acts as an alternative learning peer when a user cannot find suitable partners in a group activity. Software agents are also called Virtual Learning Companions (VLC) [Chan and Baskin, 1988].

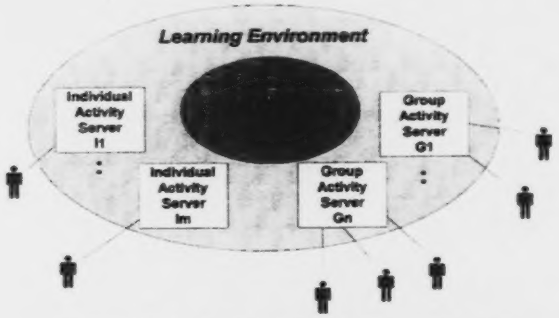

Figure 1: Basic Model of Global Learning Society

Users performing the same learning activity form a learning group, called an *activity group*. These users are then the members of this *group activity*. A group with just student members (maybe peers or tutor/tutee) form a group learning environment. In a more sophisticated design, learning may be either cooperative, collaborative, or competitive. Group learning activities can be classified into two categories according to the styles of user interactions:

- Synchronous Activities: all members are on-line at the same time, and the interactions are immediate. Examples of this include RTS [Chan and Chou, 1995] and Distributed West [Chan *et al.*, 1992].
- Asynchronous Activities: the members need not be present (before their computers) at the same time,

BEST COPY AVAILABLE

and user interactions are not immediate. This kind of interactions are very similar to those of the BBS (Blackboard Bulletin System).

A group with both teachers and students as its members can undergo distance teaching activity, whether the teaching style is synchronous or asynchronous. Some activities need just one user (usually a student, such as homework delivery and courseware reading) as its member. These activities need no group and are called *individual activities*.

3. Analysis of Global Learning Society

We give a more detailed analysis of the basic GLS model in this section. Figure 2 depicts a layered architecture of the basic GLS model. In this architecture, the ordering of the layers, from the inside out, is Society Kernel, Learning Environment (including its activities) and users. There are several databases in Society Kernel and many protocols, denoted as P1-P4, between different modules. Two important components are included in Society Kernel: Society Server and Group Server. *Society Server* is the core of GLS, which takes charge of all the operations in the society. It also communicates with other societies to exchange user activity information. The operations can be divided into three categories:

- Initialization: Society Server should be executed first as the whole society starts.
- User Interactions: Society Server has a list of all users. It delivers suitable Activity Clients to the requesting users according to different user privileges,. At the same time, it receives user commands and does further processing. All these actions will be recorded in some database.
- Group Server Invocation: The users' requests are transmitted to Group Server, and Society Server is always ready to respond.

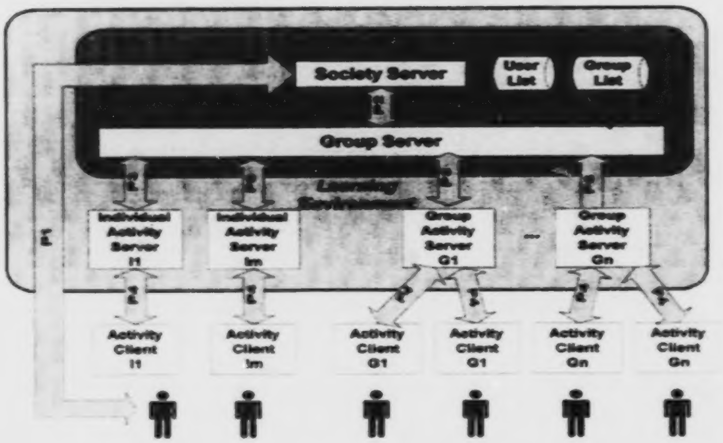

Figure 2: Analysis Model of Global Learning Society

The other important component in Society Kernel is *Group Server*. It manages all activities, including those of the individuals and those of the groups. Since each activity adopts client/server model in its implementation, the addition of Group Server makes a standard, three-layered groupware structure: group server, server and client. [Liang *et al.*, 1994] The operations of Group Server can be divided into three categories:

- Initialization: Group Server has to be executed together with Society Server as the society is initialized.
- Group Management: When Group Server received the transferred user-commands from Society Server, it has to process suitable group operations for the requesting user. These group operations may be the creation or deletion of a group, or some other operations to be executed in designated Activity Server.
- Activity Server Invocation: Actual group operations are put into practices in Activity Server. All user requests for the group will eventually be transferred to some designated Activity Server, and the action results will be kept in records.

In addition to the two databases (User List and Group List) shown in Figure 2, Society Kernel may also

BEST COPY AVAILABLE

possess some logfiles. These logfiles can be used to record the actions among user-society and society-group. Logfiles are not a main component of the basic GLS model and hence are not shown in Figure 2.

No matter how simple or fantastic model a Society Kernel is, it is only a skeleton of our GLS. The ultimate user-group interactions would happen in the Activity Server / Activity Client pair. As mentioned above, the activities that the users take part in are either group activities or individual activities. Here, the so-called *Individual Activities* are not that a user can work by himself or herself in the world, but that he or she can process some learning activities through the computer network. Activities of this sort include courseware reading, homework delivery and exercise practicing. In GLS, Individual Activities are implemented using the client/server model; that is, users use certain Activity Clients (delivered by Society Kernel) to communicate with Activity Servers in order to perform the needed activities. Users can also participate in some groups and then perform some group actions.

Basically, a user can create a new group, join an existent group, leave a group or delete a group (if he or she created it). All these constitute the basic group actions emitted by a user to Society Kernel. As for actions of special groups, Society Kernel only transfers the user command to the group (Activity Server) and let the Activity Server respond to the command. In practice, both synchronous and asynchronous group activities have the following communication requirements:

- Synchronous Group Activities: These activities require that all Activity Clients be present in front of their computers. The clients communicate through networking. If the communication bandwidth allows, they can have real-time information exchange. In practice, however, the real-time media had better be text or command. If multimedia communication such as audio or video conferencing is to be used, large bandwidth is a must.
- Asynchronous Group Activities: In addition to the bandwidth constraint, one other disadvantage of synchronous group activities is the requirement of simultaneous presence of all users. Even if this is not impossible, the requirement still imposes some inconvenience on the part of the users. This is why asynchronous group activities are more attractive in cases like BBS and WWW. To engage in this kind of activities, users need not be present at the same time. They still take part in some activities for a common goal within some specific time framework, and are still treated as a group.

No matter how the components of GLS, including Society Server, Group Server, Activity Server and Client, are designed, the only element that can integrate all these components into one coherent framework is the protocols. As shown in Figure 2, there are four different kinds of protocols in GLS: P1, P2, P3 and P4. They denote, respectively, the interactions between User (Activity Client) and Society Client, those between Society Server and Group Server, those between Group Server and Activity Server, and those between Activity Server and Activity Client.

P1 (User Registration Protocol)	Action	Course Name	Class Number	Activity Type	User Name			
P2 (Group Creation/ Deletion Protocol)	Action	Course Name	Class Number	Activity Type	Group Name	User Name		
P3 (Member Join/ Leave Protocol)	Action	Course Name	Class Number	Activity Type	Group Name	User Name		
P4 (Data Transfer Protocol)	Packet Type	Destination School	Course Name	Activity Type	Destination File	Access Type	User Name	Data

Figure 3: Communication Protocols in GLS Model

Figure 3 shows the formats of all four protocols. Action can be group creation, deletion, join, or leaving. Destination School is the server name of the school. And Access Type may be read or write. General group and member actions in GLS can be accomplished through the interactions of related protocols, such as

- Creation or Deletion of a Group: A user emits *P1 (User Registration Protocol)* to Society Server, Society Server notifies Group Server through *P2 (Group Creation/Deletion Protocol)*, then Group Server creates or deletes the group and activates the corresponding Activity Server by *P3 (Member Join/Leave Protocol)*.
- Join or Leave of a Member to or from a Group: A user tells Society Server the request (P1), Society Server then tells Group Server (by P2), Group Server checks the existence of the group and notifies the new member to the corresponding Activity Server (by P3). Then the user (Activity Client) can directly communicate with the Activity Server through *P4 (Data Transfer Protocol)*.

BEST COPY AVAILABLE

The protocols glue all GLS components together and makes the GLS Model work efficiently.

4. WWW Implementation of GLS

As network technology evolves, the realm of Internet grows ever larger. This is especially true with the hyperlink capability of WWW, which makes the whole world a connected communication net. Therefore, an example system is established on WWW to demonstrate the functions of GLS model. In this example system, a virtual school is treated as a society, with courses delivered in different learning styles to various learning groups. As Figure 4 shown, this example system contains Society Kernel, Homework Delivery Server, Learning Café Server, SoftLab Server and Data Mining Server.

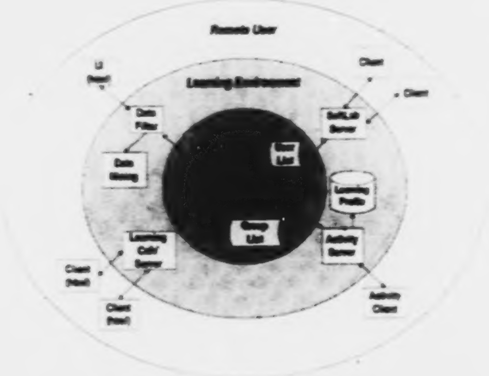

Figure 4: An Example System of Global Learning Society

In Figure 4, each component of the GLS model is built as either a Java applet, a CGI (Common Gateway Interface) program, or a system daemon. The communication protocols P1-P4 may be implemented in TCP/IP socket or IPC (Inter Process Call).

As mentioned, Society Kernel has two major components: Society Server and Group Server that are built as system daemons that run on the server side. The program structure of Society Server includes:

- User maintenance module: This module maintains a user list and controls which privilege a user can possess when joining a group.
- User activity recording module: As a user joins a group, this module records the group name, joining time and the actions the user takes.
- Communication module: This module provides communication channels with protocols P1 and P2.
- Registration module: This module allows a user to register in GLS.

The program modules of Group Server are:

- Activity Server maintenance module: This module keeps track of all Activity Servers, including the starting and stopping activities of these servers.
- Communication module: This module maintains two protocols: P2 and P3.
- Record transferring module: As a user enters a group, all his or her data records should be transferred to the corresponding Activity Server. Likewise, some actions of the users are passed on to Society Server.

As mentioned, each Activity Server in GLS model implements an activity, including individual activity, synchronous group activity and asynchronous group activity. In the example system, three Activities Servers/Clients are built to demonstrate the functions of each activity. As Figure 4 indicated, Homework Delivery is an individual activity, through which a student can send his or her homework to the instructor. Figure 5 shows one usage of our system. Figure 6 displays an asynchronous group activity, called Learning Café, in which different users can learn cooperatively or competitively in different (or the same) learning units. The different join/leave time makes this activity asynchronous. Another learning activity is SoftLab [Chung *et al.*, 1997], in which different users can cooperate in performing a virtual experiment.

There is yet another activity, called Data Mining, which is used for data collection and system evaluation (called Outcome in SPOT structure). It extracts user activity records to generate some estimate data, and tries to evaluate system performance or users' learning effectiveness. This way, we not only can improve our system to

BEST COPY AVAILABLE

fit users' requirements, but also can give learners some suggestions regarding learning activities.

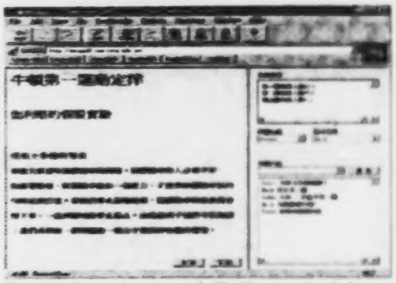

Figure 5: Homework Delivery Activity

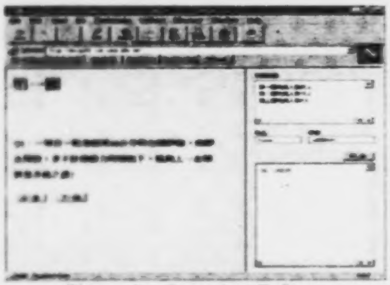

Figure 6: Learning Café

5. Conclusion

Combining the S (Structure), P (Protocol), O (Outcome), T (Technique) components in social learning systems, a basic model of GLS (global learning society) is proposed in this paper. From the viewpoint of organizational behavior, GLS model possesses a three-layered architecture: Society Kernel, Learning Environment and Remote Users. Society Kernel includes Society Server and Group Server. As users invoke some individual or group learning activities, Group Server would activate certain Activity Servers to serve the users. Then the users use Activity Clients to communicate with Activity Server in client/server style. All the functions of components are investigated and their in-between protocols P1, P2, P3 and P4 are analyzed to get an integrated GLS model. This model is implemented on WWW to confirm the feasibility and some practical considerations are listed.

In the near future, a more integrated system will be provided on our WWW site. And then some real tutoring / learning activities will be held in actual classes. Besides the three social learning components: S (GLS basic model), P (P1-P4 protocols) and T (WWW implementation), the fourth component O (Outcome, evaluation and learning efficiency) should be taken into consideration as well. This brings the issue of Data Mining into the picture.

Abstract: This paper describes our experience as teachers (and learners) in cyberspace. An evaluation of the literature on computer-mediated communication (CMC) is presented and the two major theoretical positions, the filtered-cues and social information processing perspectives, are explicated. Although generally considered divergent positions, it is argued here that they are complementary, both being required to adequately describe the potential of CMC for teaching and learning. With a desire to create enough relational connection to establish a "learning community", but still play with notions of anonymity online, we encouraged students in our subject to explore pseudonymity, adopting and playing with an alias. The subject is described together with our observations of the benefits and disadvantages of pseudonymity for education.

In her book Life on the Screen, Sherry Turkle [1996] describes the concept of *depaysement*. Appropriated from anthropology, depaysement, meaning literally to "decountrify" oneself, is defined as the experience of (re)seeing. "One leaves one's own culture to face something unfamiliar, and upon returning home it has become strange - and can be seen with fresh eyes". (p.218) Cyberspace is rich with opportunities for depaysement: we can experiment with how it feels to be the opposite sex or sexless, we can change our ethnicity or the colour of our skin, we can develop relationships with people we would never meet face-to-face (FTF); all of which enable us to experience a different perspective from which to (re)view the self and real life (RL) constructs. This potential of cyberspace is at the heart of our teaching online. Our aim is to help students, through their work in cyberspace, experience the challenging shift in perspective that is depaysement; our aim is to encourage them to (re)see the familiar and develop a critical appreciation of the potential of technologies.

Teaching in cyberspace has also given us a chance to (re)view the familiar in our educational practice, thereby using our life online to inform our FTF teaching. Several writers have already begun to note that debates about technologies are leading to a (re)viewing of pedagogy [Atkins, 1991; Spender, 1995]. Our paper therefore adds to this small, but growing body of (re)vision. Our focus is the use of the alias in online education. In a medium associated with anonymity, we explore the impact of enforced pseudonymity, that is the use of an alias, on teaching and learning.

Online Anonymity

An increasing body of work on computer-mediated communication (CMC) has grown out of our own discipline, social psychology. This literature was our starting point when we first began thinking about teaching a subject in cyberspace. Within this literature there exist two distinct theoretical positions, the filtered-cues approach and the social information processing position. Both theories offer potential insights into the use of CMC for teaching and learning.

Early work on CMC, based on what was known as the filtered-cues position, described the medium as one bereft of *social context cues* [Sproull & Kiesler, 1986]. These cues define the social nature of the situation and the status of those present and include aspects of the physical environment and body language, as well as paraverbal characteristics such as the volume, emphasis, and rate of speech. With such cues largely filtered out, CMC has been described as a lean medium that is relatively anonymous.

Although most of this early work took place in the organisational context, some research from educational settings supports the filtered-cues perspective. The benefits of online anonymity for teaching and learning have included increased equity [Collins & Berge, 1995; McComb, 1994; Ruberg & Taylor, 1995] and higher participation rates [Hartman, Neuwirth, Kiesler, Cochran, Palmquist, & Zubrow, 1995]. Without the cues that can sometimes stifle contributions, otherwise quiet students might find a voice. Howard Rheingold [1994] enthuses about the potential of this anonymity, commenting that people find "virtual communities treat them as they always wanted to be treated - as thinkers and transmitters of ideas and feeling beings". (p.26) Given that one of our main aims in teaching is to help students explore their potential as "thinkers and transmitters of ideas", CMC offers considerable possibilities.

The filtered-cues approach to CMC also noted the related presence of disinhibited behaviour online [Kiesler, Siegel, & McGuire, 1984]. Without the usual non-verbal cues and well established etiquette that exist in FTF exchanges, we are less likely to feel constrained by convention. With the applicability of FTF norms in question and the repercussions of violating such norms less immediate, CMC has been associated not only with higher levels of self-disclosure, but also more antisocial behaviour. The very features permitting greater equality allow the expression of negative emotion as Howard Rheingold [1994] explains:

> The same lack of social feedback that lowers inhibitions enough to promote self-disclosure among groups of people can also lower inhibitions enough for individuals to disrupt those groups and sometimes tear the delicate fabric of trust that has been carefully woven over months of conversation among disembodied strangers. (p. 185)

Such behaviour is the antithesis of the mutual respect that we aim to foster in our teaching. Yet the filtered-cues position interprets antisocial behaviour as an inevitable consequence of the anonymity of interactions online. Is all teaching in cyberspace doomed to outbursts of aggression? Joseph Walther [1992], the proponent of the social information processing perspective (SIP) suggests not.

Of central importance to our project was the emphasis on relationship within SIP. SIP suggested that, far from being an anonymous medium, CMC can be as deeply relational as FTF interactions; all that is required is sufficient time and message exchange. CMC is relational, Walther argues, because of our strong desire for affiliation. As essentially social beings we are driven by a need for association and connection. Although the narrow bandwidth denies us non-verbal cues, we adapt to the medium and use textual cues to form impressions of others [Lea & Spears, 1992]. When relationships are developed, anonymity and disinhibition are reduced and antisocial behaviour is less likely. It is not surprising therefore to find that flaming, deliberately insulting or provocative messages, is more prevalent on large lists where it is easier to remain anonymous rather than in private email [Thompson & Ahn, 1992, cited in Walther, Anderson, & Park, 1994].

The two positions, filtered-cues and SIP, are generally conceptualised as diametrically opposed explanations of CMC, however, both are required to adequately describe the process of cybereducation. The features of CMC do render users vulnerable to outbursts of disinhibited and antisocial behaviour, however, SIP offers strategies to counter the negative effects. The tension for us as educators is developing a level of anonymity with its concomitant benefits, as described by the filtered-cues approach, while fostering the commitment and depth of relationship, predicted by SIP, sufficient to produce a sense of community. In our attempt to juggle these demands we decided to focus the students in a conscious way on the use of the pseudonym or alias.

We hoped that the self-reflexive use of pseudonyms would have a number of advantages. In contrast to the complete anonymity described by the filtered-cues position, the use of pseudonyms creates a context of "managed ambiguity" [Jaffe, Lee, Huang, & Oshagan, 1995]. Day and Batson [1995] describe this pseudonymity as allowing "a freedom to experiment with one's usual voice" (p.42). This experimentation could be particularly valuable in male-dominated disciplines such as Engineering or Computer Science, where adopting a genderless personae or being a virtual male might give women more confidence to contribute to discussions, with attention no longer focused on the sex of the speaker. Considering the male-dominated culture of the net which can intimidate female users [Spender, 1995; Turkle, 1996], gender-masking or gender-neutrality might be used more broadly within cybereducation as a strategy to encourage female students.

Without cues to signify the user as female or male, we might feel less bound by the traditional sex-based constraints on communication. Research suggests that, although women are more likely to mask their sex than men, in a context of pseudonymity men are more likely to change their behaviour, adopting more stereotypically feminine ways of communicating, such as the use of statements that support and encourage other users [Jaffe et al., 1995]. The development of a "learning community" has been posited as central to successful virtual teaching [Wiesenberg & Hutton, 1995]. To have both sexes equally encouraging and supporting of others might be considered important to the development of this community.

Personal Identity and Community in Cyberspace

In 1996 we developed a new semester-length subject called Personal Identity and Community in Cyberspace. The subject was part of a compulsory liberal arts program. All undergraduate students are required to complete three units from the program. The aim of the subject was to explore, theoretically and experientially, the meanings of identity and community in cyberspace. For example, how might our sense of who we are be constrained in interactions where the physical body does not exist? How might it be more fully realised? What are the implications of the ease of identity play in the virtual context for RL interactions? Without conventional geographic and ethnic markers, are new kinds of communities beginning to emerge? How do these new communities inform their RL counterparts?

Our aim was to immerse the students in the technology; to have the process of the subject, that is researching and interacting in cyberspace, become the content through a practice of critical self-reflexivity. All interactions took place online, with the exception of a final FTF meeting. We used FirstClass, a closed email and conferencing system that is user friendly, allowing students to develop a high level of competency quite quickly without any training. Within FirstClass, students submitted weekly journals, discussed key themes in the subject, as well as worked on and submitted a group project. There were also places, both synchronous and asynchronous, to socialise. Our initial intake consisted of 20 students.

We asked students to select an alias at the beginning of the semester. They were known by this pseudonym in all interactions. Research suggests that our name is an important signifier of our identity [Bechar-Israeli]. However, this name is usually chosen for us. An alias or nick, unlike our real-life (RL) name, is self-chosen, and can therefore be used to conceal or highlight our sense of self. An online alias is often, although not necessarily, "chosen to hide explicit identity, yet simultaneously reveal a personal facet of the author" [Jaffe et al., 1995].

The students' first task in the subject was to write a journal entry about their choice of alias. This was their first opportunity for self-reflexive analysis. In writing about the name they had chosen they were invited to think about the process of creating an identity. Although some students reported that they didn't give much consideration to the alias they chose, as the semester progressed, they were challenged to see that names they adopted nonetheless provided powerful cues for the impressions other students formed.

Lessons from experience

The delights of pseudonymity

As predicted by the filtered-cues position, the online environment allowed some students to find a strong and confident voice. Some students commented that they were more confident and contributed more online. The most positive observation was the reduction of cultural barriers. RMIT has a high proportion of Asian students, many of whom are international students, and as a university we are continually trying to address the issues raised by internationalisation. For a number of reasons, including cultural differences in educational expectations, as well as language confidence, Asian students are sometimes quiet in class [Ballard, 1991]. Of our first intake of students 20% were Asian. One of these in particular commented on the difference between his behaviour online and in FTF classes, "Comparing to FTF I do not say much unless teacher asks me, but online I write heaps ".

Balanced against this advantage is the stress for some students of communicating using only the written word. Another Asian student, Coconut, who fell behind in his work, noted the difficulty of communicating in a completely text-based medium: "It is ... hard for someone to exchange their opinion or information through the word ... especially for someone that do not have good english background ... but, i can do very well in chinese". While the issue of written expression arises for many of these students in FTF classes, written work is generally balanced with oral papers and group participation.

We also observed that interactions across cultural groups seemed to take place more easily online. While cultural markers were often evident in expression in email messages, in the more casual real-time talk, where abbreviations and misspellings are frequent, they were less obvious. Students talked about forming relationships across cultural boundaries, when in RL they felt more comfortable within their own cultural group. The benefit of getting to know each other online without meeting FTF was commented upon favourably by many students. Ramona summarised many students' reactions in the following comment:

> I think that we should be grateful for having the opportunity to meet each other [online] and talk to them for a few months before meeting each other ... When you meet someone in real life too many things get in the way for you to be able to talk to someone properly.

Reiterating Ramona's thoughts, Cougar sent the following reflection after meeting one of the other students in RL: "I would not have gone near him ... the physical perception put me right off ... then I thought wait on a sec, if I get on so well online maybe I should give him a chance. As it turned out, it was worth it". In FTF classes, first impressions make us more receptive to the ideas and arguments of some students. This is not to say that impressions are not formed online, because not only are they formed, but our observations and experience suggest that they act as powerful schemas that can be resistant to change[1]. However, these impressions are more likely to be based on ideas and the expression of these ideas than age, race, sex, or looks. A focus on the others students as "thinkers and transmitters of ideas" was evidenced in the strong critical approach they developed to each others' contributions.

Previous experience with newsgroups as well as existing research [for example, Gregor & Cuskelly, 1994] led us to expect a certain informality in online communication. We were not prepared, however, for the level of playfulness among the students. A lot of this play took place between the characters the students created through their alias. For example, Just Another Wolf opened many of his messages with "Grrday" or "Howlo" and sent his journals as text wrapped around elaborate ascii figures of a wolf. Tiger and Cougar joked about eating Rabbit for dinner. The students were also playful - flirtatious and cheeky - with us. This playfulness was particularly obvious in the social parts of the subject, the Personal Identity Pub, an asynchronous bulletin board, and in real-time chat. Many of the students evidenced a strong sense of community in the subject and these social, playful places seemed to be important in facilitating the development of that community. Walther's hypothesis that time is required for the relational nature of CMC to develop was supported: in general those students who spent more time online, particularly in the real-time chat, were those with a stronger sense of the class as a community.

Day and Batson [1995] caution against categorising online play as frivolity and they challenge teachers to develop appropriate practices for the "different psychological environment" that is created by CMC. We were, at least initially, guilty of this categorisation, experiencing a tension between the need to allow students time to interact socially and our desire to get through the syllabus. At times we felt as if the students were enjoying themselves, but we wondered how much they were learning. We were fortunate, however, in that the process of character play was integral to the subject. Students were encouraged therefore to deconstruct their play.

Lessons from experience

The dangers of pseudonymity

Given the strong sense of community that developed, it was not surprising that commitment to the subject was high and antisocial behaviour was infrequent.[2] Consistent with SIP we observed that students who took on the

---

[1] See, for example, the classic study of self-fulfilling prophecy in a primary school by Robert Rosenthal.

[2] As in most subjects, some students demonstrated a low level of commitment, submitting very little work and spending little time online. It is, however, difficult to attribute this to pseudonymity as these few students tended to use their real name in correspondence with us. Lack of commitment was correlated with low levels of interaction early in the subject. Students who experienced difficulty with the software early in the semester and were not online to take part

BEST COPY AVAILABLE

socio-emotional roles in the group, encouraging other students to contribute, were those more likely to self-disclose. Even these students, however, engaged in playful insults, suggesting that a norm of teasing, playful provocation had been established. On a more serious level, early in the semester an alias was stolen and used to flame another student. Several students registered their disbelief at this behaviour and some discussion of the role of trust ensued. Students called on the person responsible to own up, but no one did. The incident was a significant one in the history of the class and it formed the basis for one of the group projects.

All other negative disinhibited behaviour was confined to one student, Hashmann. Hashmann was a homeboy, a rap freak with a black American accent. When Hash was online, "Da man waz in da' houz". From his first post Hashmann was aggressive. He swore, wrote in capitals, and flamed other students who made moderate and sensible suggestions. He disagreed with most comments made, including our own, and was sexist.

Hashmann was distinguished not only by his online aggression, but the persistence of his virtual personae. Other students had well developed characters, for example, Just Another Wolf sent pictures of himself in his wolf costume and wrote about his experiences in FurryMUCK, however, he moved consciously out of character when he wanted to speak as Keith rather than J.A.Wolf. Hashmann never moved out of character even in his personal interactions with us. On one particular occasion when he was reprimanded by one of us for aggressive behaviour he responded in a private email, saying "you got some nerve lady!" He seemed to delight in his enigma, stating that we did not know who he was and therefore could not presume to understand his motivations.

We found Hashmann an interesting, albeit somewhat frustrating, personae. Having him in the subject was useful in that his behaviour raised questions that were central to the subject, to life online, and, importantly, to our teaching practice. Hashmann's behaviour caused us to rethink the roles of students and teachers.

The Process of Depaysement

Our experiences in cyberspace have fed into our FTF teaching and have been instructive in shaping our plans for our second intake of students in the online subject. The use of aliases offered a rich source of information for both us and the students. In our subject the process of pseudonymity was an integral part of the content of the subject, however, our findings suggest that the use of the alias might be valuable even when self-reflexive analysis is not an explicit component of the curriculum.

Teaching in cyberspace has provided us with an opportunity for depaysement, challenging us to (re)view our FTF practice. As a result of our experiences we have (re)considered the implicit norms that we and our students have internalised. We are (re)seeing the role of creativity in teaching and learning, and (re)appreciating the value of play, and the importance of the "learning community". The process of depaysement can be an uncomfortable one, as the strategies from our FTF teaching are often tried and comfortable. Pushing beyond these takes energy and commitment, but as Day and Batson [1995] argue, "holding on to the traditional makes it harder to see the opportunities" [p.37]. We can not assume that the skills and pedagogy of FTF teaching will be appropriate in cyberspace. We have to be open to change and open to the lessons, both in their delights and their dangers, that teaching online can offer.

Abstract This study describes participants' reactions to school/university activities that were enhanced by connecting distant sites via desktop videoconferencing. During this study teachers, school students, university faculty, and preservice teachers designed and/or conducted activities that provided for individuals to collaboratively problem-solve and obtain multiple perspectives during learning. The study describes participants' reactions to desktop videoconferencing activities and identifies and discusses variables that promote and/or limit such activities.

Background and Objectives

Distance technologies offer opportunities for linking two or more classrooms together so that students can collaboratively problem-solve and obtain multiple perspectives during learning. In addition, distance technologies provide teachers, preservice teachers, and university faculty with opportunities to collaboratively design curriculum and activities. However, most distance technologies are expensive, difficult to access, and complex to manipulate [Newby, 1996].

Desktop videoconferencing (DVC) allows users to participate in meetings with one or more people at distant sites using a personal computer, videoconferencing software, and a digitizer camera. To support our university/school activities we had affordable QuickCams™ coupled with free CU-SeeMe™ software at various school and university computers. CU-SeeMe™ software provides for conference participants to see and hear each other and in addition to write messages in a talk window.

Desktop videoconferencing's affordability, accessibility once purchased, and ease of use make it an excellent means for supporting communication needs of partnership programs. It appears to be an important technological innovation for connecting teachers and students. However, so far DVC has received little research attention. This study describes school activities that were enhanced by connecting distant sites via DVC and participants' reactions to those activities. Moreover, the study identifies and discusses variables that promote and/or limit such activities.

Desktop videoconferencing facilitated activity in two funded projects, GTech and Cultural Connections. In GTech teachers in nine middle and junior high schools collaborate with university professors to develop curricular activities that integrate science, mathematics, and technology. In Cultural Connections teachers, professors, and students conduct curricular activities via distance technologies to enhance student achievement, self-esteem, and multicultural understanding.

Theoretical Framework

Reform efforts in education have supported schools and universities as complementary partners in the preparation of teachers and the development and delivery of effective instruction in schools [Goodlad's Postulates, Professional Development Schools, 1990; Sizer's Coalition of Essential Schools, 1993; The Holmes Group, 1990; and The Center on Organization and Restructuring of Schools, Prager, 1992]. In addition, cross-classroom collaboration among school students is being encouraged as a means for learning language skills, new perspectives, increased multicultural understanding, awareness in the international arena, and cooperative patterns for tackling problems and issues [Riel, 1995]. Considering the increased support for collaboration, one would expect such partnerships to flourish. But the seemingly simple task of getting people together can be logistically difficult. Distance technologies might minimize the limitations of time and distance, and reduce travel and personnel expenses.

While several studies have described videoconferencing activities to support school/university and cross-classroom partnerships [Cable in the Classroom, 1995; Cifuentes, Sivo, Reynolds, 1997; Gibson & Gibson, 1995; McDevitt, 1995; Perraton, 1993; Riel, 1995; Strommen, 1995], little research has been done to explore the instructional utility of desktop videoconferencing. In this study we explore the extent to which participants find DVC educationally rewarding, factors which contribute to sense of reward, what makes DVC activities work, what limits such activities, and how such activities can be improved.

Desktop Videoconferencing Activities

Through grants from General Telephone and Electric (GTE) and The Center for the Study of Collaborative Learning at Texas A&M University, GTech and Cultural Connections projects were initiated. In the contexts of those projects desktop videoconferencing facilitated three different year-long school and university collaborative activities. In one activity, preservice teachers connected with inservice teachers who formatively evaluated classroom lessons that they developed as part of their teacher training. The technology provided preservice teachers with a virtual field-based experience. In another activity, teachers and university faculty met via desktop videoconference to collaboratively develop integrated thematic units for middle school science and math with an emphasis on technology utilization. During the third activity, middle school age students and school teachers met to collaboratively solve academic problems and share cultural experiences.

Methods

Participants

Participants in the study are 54 middle-school or junior high school teachers involved in GTech and Cultural Connections DVC activities and the many students in their classrooms. The teachers incorporated the DVC activities in their mathematics, science, English, and social studies classes or in their homerooms.

Design

This study was conducted using both quantitative and qualitative research methods with the four researchers collaborating in survey and interview design, data collection, analysis, and development of meaning. Contributing variables to overall sense of reward included (1) goal clarity, (2) professional goals met, (3) gain of perspective, (4) pursuit of interesting topics, (5) facilitation of communication, (6) facilitation of multicultural understanding, (7) provision of opportunities unavailable otherwise, (8) facilitation of learning, (9) ability to see each other, (10) receipt of recognition, (11) making job easier, (12) enjoyment by students, (13) enjoyment by teachers, (14) ability to dialog with other professionals, (15) ability to see and hear distant partners, and (16) ease of use. Qualitative analyses of open-ended survey questions and interviews related to perceived benefits and limitations will be used to identify variables that either contributed to or limited the DVC activities.

Data Sources

All teachers and students are given a survey to assess the perceived quality of the activity as facilitated by DVC. This Desktop Videoconferencing Survey (DVCS), [Cifuentes, 1996] was developed from several interactive video conference evaluation instruments prepared for a distance education course in response to reading *The development of an instrument to measure attitudes toward televised courses* [Biner, 1993]. Two distance educators confirmed the instrument's content validity. The two-page survey is comprised of both five-point Likert items and open-ended questions. There are 13 Likert items designed to represent variables pertinent both to the *activity process* and to the *activity's impact upon its stakeholders*. The first item on the DVCS, the item of most concern, elicits the extent to which the respondent feels that the activity is rewarding, while the remaining items address the relevant activity variables described above. Participants are asked to circle the most appropriate response, which ranges from "strongly agree" (5) to "strongly disagree" (1).

The four open-ended questions in the DVCS follow the Likert items and are designed to allow partnership stakeholders to express personal reactions to the partnership. The questions address the perceptions of preservice and inservice teachers and school administrators regarding: (a) what they learned from the activity; (b) what made the activity work; (c) the factors limiting the activity; and (d) what would improve the activity. Responses to the open-ended questions will be interpreted with respect to how desktop videoconferencing facilitates learning.

At several times during each semester the researchers met or corresponded with participating teachers to discuss perceived benefits or limitations of the activities. Notes taken during these sessions served as an adjunct data source.

Procedure

The data collected for this research were generated during project implementation, when teachers and students participated in desktop videoconferences. A sample of ten participating teacher filled out the DVCS. Likert item responses were tallied while open-ended question responses were semantically interpreted and categorized. In addition, researchers and teachers involved in the project met on several occasions during each semester to discuss the progress of the activities. One of the researchers took notes during meetings.

After lengthy discussion among the researchers about the qualitative survey data and contents of meetings, they achieved consensus regarding the findings. Triangulation is used as the method of analysis to provide powerful evidence of credibility: The researchers came to the study with varied backgrounds and experiences, and engaged in analytic discussion about the data. They differed with respect to age, faculty-student status, and formal background (e.g., educational technology, science education, and mathematics education).

Results

Implementation of activities was ongoing for two semesters. As a result of the collaborative activities via desktop videoconferencing, preservice teachers, inservice teachers, and students had rewarding experiences that they would otherwise not have had. While participants generally agreed that the activities had positive effects, they acknowledged that distance technologies cannot replicate face-to-face, live interaction.

All participants reported that they found DVC educationally rewarding. Factors that contributed to sense of reward included the abilities to "interact with teachers from other places", "bring the world and other classrooms across the state and nation into our school", and conduct "face to face research." Teachers commented that they appreciated the increase in technological skill for themselves and their students. One teacher liked "dealing with peers outside of the school setting" and one teacher liked "the ability to communicate immediately and ask questions directly to those "in the know." When comparing DVC to large-group interactive videoconferencing the four teachers who had done both large-group and desktop videoconferencing with their students described DVC as much more "personal" and "individualized".

Limiting factors for use of DVC, especially when compared to interactive videoconferencing included limited access, time, technical skill, and audio/visual clarity. Teachers expressed the problem of managing the learning activity when "only a few students can access the computer at one time." Others expressed the problem of limited access to the Internet. In addition, coordinating meeting times with distant partners was time consuming and complicated. Two teachers expressed the need for "set up times for people to interact" and time for "pre-planning of lessons or research." Two other teachers expressed a need for 'more training and experience with people that are comfortable using" DVC. In a discussion teachers agreed that they needed more sites with which to interact, access to more cameras, and faster modems. Several teachers described problems with audio and/or video clarity once on the system.

The ten surveyed teachers briefly described the ways that they used DVC as follows: Three teachers said that their students used DVC to interview distant students. Three others' students talked to students to learn about other cities in other states. A couple of teachers used DVC for "class presentations. Two teachers used DVC to critique and formatively evaluate university preservice teachers' multimedia lessons. one teacher used it to make presentation and to "interact with other teachers as a part of her own professional development."

In addition to rating DVC as rewarding, surveyed teachers felt positive about goal clarity, and DVC as a facilitator of communication and provider of otherwise unavailable opportunities. While most surveyed felt that their students learned from the opportunity to meet with and see distant others, some felt neutral about its benefits to their students. Likewise, while teachers generally enjoyed DVC and felt that their professional goals were being met by the opportunity to gain others' perspectives, pursue topics of particular interest, and dialog with other professionals, some felt neutral about its professional benefits to them. Teachers were less positive about the amount of recognition they get for using DVC, its contribution to job ease, and most significantly for a group of 4 teachers, their inability to hear the audio clearly.

One of the most positive findings was that eight teachers strongly agreed that DVC facilitated cultural understanding while only two were neutral on this point. Also, eight planned to continue using DVC while two were neutral. No participant felt negative about DVCs effects or its future application (see Table 1).

Item	SA	A	N	D	SD
Sense of reward in teaching	5	5			
Sense of reward for students	5	4	1		
Goal clarity	4	6	1		
Professional goals met	3	4	3		
Gain of perspective	3	3	4		
Pursuit of interesting topics	4	3	3		
Facilitates communication	7	3			
Facilitates cultural understanding	8		2		
Provides opportunities we wouldn't otherwise have	7	3			
Facilitates learning activities	8	1	1		
Meeting with distance partners facilitates learning	6	3	1		
Being able to see each other facilitates learning	6	3	1		
I receive recognition for participation	3	2	4		1
DVC makes my job easier	2	1	6	1	
My students enjoy DVC	8		1	1	
I enjoy DVC	5	4	1		
DVC facilitates dialog between professionals	2	1	7		
I could hear the distant partner clearly	1	3	2		4
I could see the distant partner clearly	3	6	1		
DVC is user friendly	3	4	3		
I will continue to use DVC in my classroom	4	4	2		

Table 1: Responses to questions about the rewards of desktop videoconferencing. SA=strongly agree, A=Agree, N=neutral, D=disagree, SD=strongly disagree

Educational Importance

While time and distance limit the practicality of school/university and cross-classroom collaboration, distance technologies facilitate rewarding interactions between preservice teachers, inservice teachers, and students for virtual field-based, collaborative, and multicultural experiences. Identifying factors that contribute to or limit successful application of distance technologies is an important area of investigation for anyone interested in instructional interactions via distance technologies.

Abstract In this study we explored the effectiveness of distance learning and multimedia technologies in promoting multicultural understanding among teachers, thereby facilitating increased: 1) school achievement, 2) self-esteem, and 3) multicultural understanding among students. In addition, in collaboration with university researchers, teachers developed both curricular activities and identity-forming multicultural activities for their students to conduct over the distance. Students partcipated in collaboration activities and shared multimedia files with other students via interactive videoconference, desktop videoconference (CU-SeeMe), and computer conference. In this cross-classroom collaboration, predominantly Hispanic students in the Rio Grande Valley of Texas communicated regularly with diverse students in two schools hundreds of miles to the north. Using qualitative research methods, we discovered that the participating teachers and students developed communication and leadership skills as they increased cultural sensitivity.

Objectives

Learner-centered schools must honor diversity and emphasize how similarities foster unity [Texas Education Agency]. Therefore, students, teachers, and administrators must build on similarities that strengthen bonds, among the members of the learning community. In this study we explored the effectiveness of distance learning and multimedia technologies in promoting multicultural understanding among teachers, thereby facilitating increased: 1) school achievement, 2) self-esteem, and 3) multicultural understanding among students. Cultural Connections is an extension and expansion of Project Footsteps [Cifuentes, Metcalf, Webb-Johnson, Murphy, & Davis, 1996]. As with Project Footsteps, the purpose of Cultural Connections is to promote collaboration and cross-cultural understanding among secondary teachers and students across geographical distances using distance learning and multimedia technologies. In this cross-classroom collaboration, predominantly Hispanic students in the Rio Grande Valley of Texas conferred regularly via distance technologies with diverse students hundreds of miles to the north.

Teachers collaboratively developed curricular multimedia/distance learning activities for their students. Cultural connections gives teachers meaningful applications of technology in their classrooms and opportunities to build professional relationships with teachers across diverse school sites. The project provides students with the tools to explore and present who they are to culturally diverse audiences. Students have opportunities to respond to presentations by other distant students' and to get feedback from others about their own presentations in order to heighten awareness of diversity.

Theoretical Framework

Low school achievement and high drop-out rates among disadvantaged groups are closely connected to social, cultural, and geographic isolation. Isolation inhibits personal identity and growth by limiting horizons and awareness of possibilities. To prepare for the increasingly interconnected world of the 21st century, teachers need to help students become more aware of various cultural traditions and to respect and appreciate their own and others' cultures [Greenfield, 1996; Zeichner, 1995]. Developing respect for one's own culture helps to overcome lack of pride and confidence, which obstructs achievement and school completion [Slavin, 1995]. In addition, cultural exchange can foster understanding among people of diverse cultures [Banks, 1994].

Distance technologies expand the range of opportunities for students to build relationships with people of different cultures. In the current social-constructivist conception of learning, "education is the shared way of thinking about one's self, the community, and the world" [Riel, 1995, p. 219]. Schools might play a significant role in nurturing students' positive identity formation by providing them with opportunities to build distant relationships. In order to transform into more tolerant and respectful citizens, students need to develop relationships with people from diverse cultures and backgrounds (Moffett, 1994). Geographical and cultural isolation can limit opportunities for relationship building beyond one's culture. However, cross-classroom collaboratives allow students to connect with distant others from around the world. The collaborative learning process has the potential to transform individual participant's perspectives from parochial to global [Cummins & Sayers 1995; Metcalf, 1994]. In Cultural Connections, multimedia software and distance technologies were used to eliminate isolation. Student development of multimedia portfolios and cross-classroom collaboration were meant to foster the building of multicultural relationships while honoring the strength of diversity and emphasizing how similarities unify.

The Project

In collaboration with university researchers, teachers developed identity forming and multicultural curricular activities for their students to conduct over the distance. For instance, they developed multimedia activities from writing activities in *I Thought I Was from Another Planet* [Dresser, 1994], which was designed to help students develop authentic writing voices and heighten their sensitivity to our multicultural world. Students did the activities, which involved writing and distance collaboration, and ultimately produced multimedia presentations of their work which they shared over the distance.

Another activity involved a distance open forum to discuss the pros and cons of school uniforms. Students conducted library and Internet research on the topic; they surveyed campus students and faculty; and they formulated, developed, and presented persuasive arguments across the distance.

Cultural connection used the combined power of multimedia and distance technologies to motivate diverse and geographically separated students to visualize and write about and share with each other who they are. In HyperStudio™, one of the multimedia software programs used by students in the project, students wrote and visualized volumes about their home lives, their goals, their thoughts and values, their likes and abilities, and their stories. The scrolling text option allowed them to place several essays in their multimedia portfolios. Students were forced to reflect critically upon their understanding of their experiences in a social context beyond their immediate communities. They shared multimedia files with others via interactive videoconference, desktop videoconference (CU-SeeMe), and computer conference. Presentations were projected before a class, viewed individually, and/or viewed in small groups. Files were stored by students as they generated ideas and received feedback from each other. In addition, and perhaps most importantly, because multimedia software files are easily edited and revised, students could change their presentations as they themselves grew and changed.

Methods

Cultural Connections included Berta Cabaza Middle School in San Benito, Texas, which is located in the Lower Rio Grande Valley; Jones Intermediate School in Waller, Texas, which is located about 350 miles to the north of San Benito; and Somerville Junior High School in Central Texas. Participants in this study included teachers and their students, school counselors, school principals, university faculty at Texas A&M, and a trainer at an Educational Development Laboratory. Sixteen teachers at Berta Cabaza, six teachers at Jones Intermediate and two teachers at Somerville Junior High who teach math, science, language arts and social studies conducted Cultural Connections curricular activities. A counselor at Berta Cabaza partnered with a counselor at Somerville Junior high to conduct guidance activities. School principals, and university faculty facilitated the project. This study included descriptive statistics associated with the ten fifth grade students from Jones Intermediate and twelve eighth grade students from Berta Cabaza who were active in the project throughout the 1996-1997 academic year. All student populations in partcipating schools were racially and culturally diverse, and participating students equitably represented the student populations of each school. The school and university partners were equipped with interactive compressed video systems, HyperStudio™ software, Internet connections, CU-SeeMe™ software, and FirstClass™ computer conferencing software.

Design

This study reports participants' reflections upon Cultural Connections and on the progress of one partnership between two teachers, one at Berta Cabaza and one at Jones Intermediate, toward meeting project objectives. This investigation relied on ethnographic methods. Data sources included videoconferences, student portfolios, student interviews, students' and teachers' reflective journals, evaluations of the annual videoconference, and student records.

Participating students prepared presentations that they delivered orally via videoconference to partners at distant schools. In addition, participating students created and maintained multimedia HyperStudio™ portfolios containing collected works about their homes, thoughts and values, goals, likes and abilities, and stories. The portfolios were under continuous construction and reconstruction by the students and served as valuable disclosures of adolescents' feelings about their experiences with distant partners.

We interviewed participating students and spent time as participant observers in the classroom during distance activities and multimedia development, keeping records of our experiences and observations. We asked such questions as, "What are you learning from developing your multimedia portfolio?" "What are you learning from meeting with your distant partners?" "What are you learning from seeing distant others' portfolios?" and "In what ways are you similar and/or different from your distant partners?"

In addition, students and teachers kept reflective journals of their experiences, observations and insights during and after implementation of the project. These journals served as rich resources, as the teachers were able to report on observed changes in their students whom they saw on a daily basis throughout the year.

An Annual Distance Learning Conference has been an important benchmark for Cultural Connections. For two years this conference has brought participating teachers and facilitators together for planning and technology training. The final activity at the conference has been filling out conference evaluations. These evaluations provided insight into teachers' attitudes toward the project and anticipated and felt effects of the project.

We analyzed and evaluated the contents of the videoconferences, multimedia portfolios, interviews, reflective journals and conference evaluations for recurrent themes regarding issues related to the effects of the technology on (a) school achievement, (b) enhanced self esteem, and (c) enhanced multicultural understanding.

We triangulated the data by obtaining multiple points of view from our own observations of the students and their work, teachers' logs, and principals' observations.

In addition, we are collecting descriptive data regarding student achievement on the Texas Assessment of Academic Skills (TAAS), attendance, conduct, and discipline referrals. Later, we will compare the year prior to Cultural Connections participation with the year of participation to determine the extent to which project participation made an impact upon those factors.

Results

Descriptive statistics that would provide evidence regarding the impact of the project on academic achievement and self-esteem are still to be identified and will be included in later reports; 1996-1997 academic reports will be completed in May of 1997. At that time we will report the statistics in a table and analyze the results. However, the other data souces alone reveal positive effects of the project.

Observations during videoconferences, contents of student portfolios, interviews, and reflective journals, and contents of teacher reflective journals and videoconference evaluations all provide evidence that Cultural Connections enhanced the teaching experience while increasing students' self-esteem and cross-cultural understanding. The themes of growth, empowerment, need for mentorship, and comfort with technology emerged from the various data sources. Each of these emergent themes indicate that the project was a powerful initiator of positive change.

Increased Self-Esteem

Teachers reported that they observed increased poise, communication and leadership skills, and technology proficiency among students. Students involved in Cultural Connections grew and matured in many areas, including increased cultural sensitivity. A teacher reflected on her experience and observations saying, "The positive relationships and friendships that have grown out of Cultural Connections are so powerful....As our students communicate via distance technologies and develop projects, they become more effective collaborators, communicators, writers, researchers, analysts, and artists." One student offered, when asked what she was learning from the project, "Technology! The wonders of it!" Another student indicated that her distance learning experience was so valuable it was worth sharing: "I can go home and share the cultures with my family."

Increased Mulitcultural Understanding

We found that distance learning and multimedia technologies proved effective in helping young adolescents make sense of their experiences and in promoting multicultural understanding. For example, after several videoconference interactions one student wrote, "Distance learning helped me to understand other cultures. I also made friends through the connection. It helped me understand what the future will be," and another explained, "I interacted with people of differenct races. It was fun meeting new people, and getting over my shyness for speaking in front of people." Several students noticed similarities between themselves and the distant students; "Our culture is not much different from theirs;" "We all get shy and nervous sometimes, but we also know that we are comfortable with each other;" "We all want a good education." Other students highlighted differences (perhaps based on misconceptions). For instance one student said, "They seem higher class because they are Anglo. They don't have to worry about fights and gangs because there aren't as much. You see them and it's like they have no problems at all." That same student said that the only similarity she could see was that she likes volleyball and one of the distant students does too.

Perhaps the project will have the power to dispell misconceptions among participants. One counselor wrote, "Role playing each site's different struggles, and then discovering solutions between the two locations is exciting.Somerville students realizing that San Benito students deal with the same adolescent difficulties...There are no barriers between the 300 miles that separate us."

A teacher said that her students, who were entirely Mexican-American, reacted favorably to becoming acquainted with students from other cultural backgrounds. She observed, "As I viewed a videotape of the conference, it was evident that my students were not used to listening to or conversing with Black students.... It was not an instance of racism, but a clear-cut instance of pure curiosity that had shown on their faces.... One of my students seemed prideful in announcing that he was the Black student's key pal." Students who tended to be absent attended school more regularly in order to participate in video conferences, and their personal grooming habits improved. One student with serious discipline problems improved his behavior and his grades in order to participate. In addition, observation revealed that participating students became leaders among their peers.

Educational Significance

Dewey (1938) [Dewey, 1938] defined growth as the ability to secure meaning from experience and to act in ways instrumental to the achievement of worthwhile ends. In Cultural Connections, diverse students across Texas collaborated on multicultural activities which helped them grow. Cross-classroom collaboration made it possible for young adolescents to expand their world-views in preparation for contributing in our increasingly multicultural environment. This project demonstrates that in networked classrooms students can connect with people from around the world to learn about and from the perspectives of others and to increase their multicultural understandings.

Abstract : The purpose of this paper is to give an overview of some initiatives taken in the area of information technology and education within the framework of the European Union. The authors identify trends and describe challenges faced by the European educational community in the implementation of a new vision of the schools of tomorrow. More specifically, the authors describe the process by which projects are launched at the European Union level followed by a description of transnational and national activities. Finally, a more in-depth description of initiatives taken at the European industry level will be presented with special emphasis on the European Round Table of Industrialists (ERT) projects. Highlights and general trends which emerged from interviews conducted during the study regarding the vision for the schools of tomorrow will be presented.

I. Initiatives at the Level of the European Union

The European Commission (EC) operates at the very heart of the European Union. Its first task is to initiate European policies, in close partnership with the other European institutions and with the Governments of the Member states. The European Commission is divided into 24 Directorates-General (DG). These DG's represent broad areas of societal issues. The work of DG22, for example, encompasses activities concerning Education, Training and Youth. In the past large programs have been launched (and are ongoing) like Socrates, aiming at promoting European cooperation in Education, with as specific activities e.g. to promote the intercultural dimension of education and to encourage contacts among pupils of all types of schools. One area where the EC actively promotes cooperation is in Open and Distance Learning. The EC typically stipulates conditions under which grants can be obtained to participate in the program; e.g. partnerships between different European countries and between different actors in the field involved. Other big programs in the field of education are Leonardo daVinci (for training), and TEN which supports the development of communications and telematics applications. Most recently the EC has launched the action plan for a European education initiative (1) which aims at accelerating school's entry into the information society by giving them new means of access to the world, (2) which encourages the widespread application of multimedia pedagogical practices and the forming of a critical mass of users, products and educational multimedia services. The necessary funding will be obtained from a variety of sources within the different programs of the EC. However, the EC encourages permanent partnerships between public and private sectors for channeling resources as well.

II. Initiatives at the Transnational level : a Virtual University for Europe

EuroPace2000 is a trans-European network of universities, enterprises and organisations with an interest in the field of distance and continuing education and training. EuroPace2000 has 60 member organisations all over Europe, 45 of which are universities. By using various models EuroPace2000 demonstrates and develops the potential of telematics for the European university of the future.

III. Initiatives at the National Level : The Swedish Example

A few years ago the Swedish government formed the "Foundation for Knowledge and Competence Development". The foundation operates with a fund of approximately US$ 1 billion and has three major tasks : (1) support research at small and medium-sized colleges, (2) favor exchange of knowledge between universities and companies, (3) increase the use of information and communication technologies (ICT) in society. We will elaborate on this third task.

To achieve the goal of increasing the use of ICT money is mostly spent on projects in schools. The Swedish program for the advancement of ICT in schools spends more than US$ 100 million over a period of three years. The program started in late 1995 and is concerned with schools for children from 5-19 years old. The main objective is to reform the Swedish school system. Therefore the basic criterion for supporting projects proposed by schools has been the type of pedagogical approach adopted. Financial support is given to projects where the role of teachers and students changes. The approach must be student-centered (based on the questions and initiatives of students) rather than teacher-centered. It is not the number of computers that is decisive for gaining support, however, all projects funded should integrate ICT in their new approach. The Foundation believes in ICT as a tool for the student to search for the information needed to construct his/her knowledge in collaboration with other students inside and/or outside the school.

The Foundation proceeds as follows :

(1) School development projects

The foundation supports more than 70 projects all over Sweden. The local administration pays 50% of the costs. Money from the Foundation may not be used for the purchase of hard- and software. It should be spent on the education of teachers, extra employees and so on. At present, the Foundation supports 27 big projects with a maximum of $750 000 per year (cities, counties) and more than 40 smaller projects with a maximum of $150 000 per year, in both cases for three years.

(2) Teacher Training

The Foundation provides $11 million to introduce teachers all over Sweden to a new way of teaching.

(3) Seminars

Now that the projects have been chosen and are set up, the Foundation focuses on the dissemination of the results of these projects to other schools. This is done by arranging seminars and conferences. In addition, a newsletter is produced and distributed to all schools in order to give all teachers an opportunity to know what is going on.

Seminars are arranged for :

- Politicians. Local politicians are informed by colleagues who have decided to invest in schools wheere ICT is introduced in the learning process. The goal is to stress the importance of reforming education all over the country. Pedagogical and technical experts (university professors) support this message.
- Teachers. Teachers with experience of using ICT tell their less progressive colleagues hwo and why they have used ICT in their school.

(4) Educational materials

Great efforts are made to support the production of both non-commercial and commercial educational material.

The typical non-commercial production is an educational web-site. For example : three-dimensional pictures from the particle-collision experiments in CERN are made available on the net. The goal of the commercial program is to support a Swedish educational multi-media industry. International cooperation is favored, the Swedish market being probably too small for profitable investments.

(5) Research

Research on IT-didactics is supported in seven universities.

IV. Initiatives at the European Industry level : the European Round Table of Industrialists

The European Round Table (ERT) is a grouping of 46 chairmen of major European companies, representing a wide range of sectors of industry and coming from 16 European countries. Their main objective is to strengthen Europe's economy and improve its global competitiveness. Therefore, the ERT invests (among other activities) in research to make wide-ranging proposals for practical policies in order to contribute to the progress of the European economy. They are concerned with all major fields in society : *education*, employment, environment, export controls, infrastructure, North/South relations etc. In education, their previous report "Education for Europeans : Towards the Learning Society" [ERT 1995] has circulated widely to European and national decision-making bodies, to national and international organizations and to the general public. After this study was produced and was very well received it became apparent that a follow-up study was needed which would focus on the use of information technology in learning.

ERT study : "The use of information technology in learning : Investing in Knowledge"

The first ERT study stressed that there is an increasing gap between economic and social realities and the output of our education system. This follow-up study "Investing in Knowledge : The integration of Technology in European Education " [ERT 1997] focuses on the necessary educational reform in Europe in order to prepare its citizens for the knowledge society and to narrow that gap. Technology is not perceived as the driving force for this reform, but its potential needs to be explored as a tool or an instrument to support the necessary changes. The human perspective prevails and implications of introducing information and communication technologies are investigated at the level of the individual learner, the teacher, the educational leader and the learning community.

The ERT study was based on an extensive review of the literature and survey of 65 experts in 9 different fields of education[1] spread across Europe. The purpose of the survey questionnaire was to gain a qualitative insight into the problems, opportunities and challenges for education, related to knowledge and technology (r)evolution as perceived by the different actors in the field of education. The results of the interviews are meant to complete the knowledge extracted from the literature search and the expertise of a scientific committee. Different methods for onducting the interviews were used : face-to-face interviews (7), video-conferencing (27), telephone (20) and e-mail or written responses (11). The method of interviewing was a semi-structured direct interview.

V. Highlights, Trends and Challenges emerging from the Study.

1. The changing role and status of students and teachers leading to a need for teacher training

Learning in the future will require more self-regulation, self-discipline, collaborative learning, flexibility and creative thinking which will affect the role of the learners. Based on the judgement of the interviewees, the fears of teachers of being superseded by technology are clearly unjustified. The majority of experts (72%) considers face-to-face teaching and computer-base teaching complementary and therefore equally valid, depending for example on the subject to be taught or the type of technology used. A minority (28%) declares technology-based learning to be clearly inferior. For the majority of the respondents new technologies primarily are an additional learning tool.

A. New roles for teachers

Although consensus is attained on the enduring importance of the teacher in the learning process, the question still arises whether the role and status of teachers are subject to important changes. An overwhelming majority of the interviewees agreed with the idea that a teacher should become more of a "guide" than an information-deliverer. The concepts of *organizer, architect, coach, counselor, regisseur, resource manager, mentor, shepherd, moderator and facilitator* were used to describe the teachers of the future. Interestingly, a number of experts argue that this new role by no means eases the job of a teacher; on the contrary the demands on his/her competencies are growing and working with technology implies that there are incremental tasks to do above the face-to-face teaching. Teachers will have to master new technologies, but knowledge of the basic subject content remains equally important.

For many teachers these changes produce tensions, however their biggest frustration seems to be the lack of training in using new technologies.

---

[1] The different fields in education are : university, open university, educational administration, industry, publishers, headmaster - (secondary, primary schools), teachers (secondary, primary schools), teacher training

Teachers need the following skills and competencies to use new technologies effectively :interpersonal communication, planning skills, collaboration teamwork skills (coordinating groups and interaction is more easy to achieve in a face-to-face setting), native language (and English) proficiency, writing skills, organizational skills, feedback skills, technical competency, seeing the big picture (e.g. being able to combine all fragmented information provided by the students)

university professor, France

B. *Teacher Training in New Technologies : barriers, content, modalities and recommendations*

Teacher training was vividly discussed when the interviewees were probed with statements concerning that issue. Although it's interesting to look at the number of agreement and disagreement obtained with these statements, it is more useful for our purpose to analyze trends in the answers provoked by the statements.

(a) main barriers to the adoption of new technologies

- there exist large psychological barriers to try and use computers and multimedia
- it is most difficult to change the pedagogical beliefs underlying teaching (student-centered or teacher-centered approach), as long as these stay the same, introducing multimedia and telematics will not affect the educational process. Fullan [Fullan et al. 1991] indeed confirms that educational materials and pedagogical methods are easier to change.
- (especially for older teachers) it is difficult to change deep-rooted mental structures on the "art of teaching"
- teachers are afraid of losing authority and class control because they believe their competency to work with computers and multimedia is inferior to that of the students
- the rapid pace of change in computer infrastructure and software results in "technical paralysis", teachers and schools cannot keep up with the speed in progress

(b) content of teacher training

- first, teacher training should motivate teachers and transform negative attitudes into the positive belief that teaching will be enhanced by the introduction of new technologies
- there is agreement that teacher training should provide teachers with the correct pedagogical skills to use multimedia and telematics in their own lessons. This is in general considered to be a priority in teacher training
- a question mark is put on the degree of technical know-how a teacher should have in order to use multimedia in his/her lessons

(c) modalities of training

Professional development in Europe isn't quite as widespread and systematic as in most places in the USA. Hence the concern from most of the interviewees on the following issues :

- the number of teachers to be trained per educational institution; should all teachers be trained simultaneously or should the most innovative teachers be trained first to later share their knowledge with their colleagues
- the timing of teacher training; ideas of sabbatical leaves, being trained in companies, are launched

Training is needed and not short training sessions grabbed in the evenings but a full and planned program when teachers are relieved of their teaching duties for large blocks of time

secondary teacher, UK

- training is wasted if it is not accompanied by giving the teacher enough time to implement their use of IT, and/or are even discouraged afterwards to apply the skills acquired in a content driven curriculum

(d) recommendations and conditions for success

- schools must provide sufficient infrastructure; e.g. one computer per teacher in school and access to the internet
- disseminate models of success and confront teacher with emergent good practices
- creation of a *teacher community*, e.g. in networking with other educational institutions at the local but by preference even at the European level, where teachers can exchange ideas, experiences and information. This will enhance experimentation and innovation and broaden ideas across Europe

2. Educational Settings of the Future

The interviewees supported the following statement in the questionnaire : "The introduction of information technologies in the institution demands a systematic approach , characterized by teamwork (including principal and teachers, among others) and it is primarily oriented towards school middle management (e.g. an activity coordinator) as the "drive" for change. However technologies can never be the trigger of real educational changes, they are only the medium that facilitates actual educational innovation.

A. The new principal : a (wo)man of vision, inspiration and cooperation

The experts stress the importance of the role of the principal of the future. He/she will have to be the driving force for the changes in the educational system and for the implementation of innovative thinking.

> *I have seen a whole school improving simply because the principal found the possibilities e-mail can create.*
>
> teacher trainer, UK.

The following profile is desired :

- principals become managers; they have to invest in management techniques and preferably spend some time in a company
- principals are not kings in a hierarchical monarchy : there is a need for an open culture and decentralized decision making : (1) teamwork with teachers, (2) possibility to engage outside experts when needed
- they develop (possibly in teamwork with their teachers and/or within a network of headmasters) a vision on the educational mission of their institution and make it operational in a strategic quality plan; they inspire all layers of their institution to adopt and realize that plan
- they are very flexible and adapt to changing demands from the society, again this refers to the openness of the culture
- they firmly support teachers in the adoption of new technologies by creating a psychological and physical space to experiment and try out new ideas; this might involve flexibility in the time-tables, providing the necessary infrastructure etc.
- they spend time on fund-raising since governmental funding becomes insufficient; e.g. by seeking partnerships with business. Skills in negotiating becomes a must
- they fulfill a public relation function towards the outside world; e.g. by sensitizing parents, local governments, local organizations (youth work etc.)

It is clear that the principal cannot assume all these tasks without things being changed at the macro-level of education. It is important that schools receive support at the governmental level of the educational system.

> *The management of an educational institution needs the power to make changes. Government has to take away barriers to innovation while giving schools autonomy.*
>
> open university, The Netherlands

B. Strategic management of resources

In essence, strategic management of resources should be a priority for the principal. He/she will have to be concerned with

- time management (e.g. flexibility in time-tables)
- management of space and infrastructure (e.g. retrofitting, space to accommodate cross-curricular activities and teamwork)
- human resources management (e.g. technical support for teachers, support staff for issues other than technical problems (e.g. new examination structures), providing teachers with larger pedagogical freedom and support them to engage in cross-curricular work)

- financial management issues; e.g. the majority of interviewees agreed that financing is a major problem in these effort to renovate education. The implications are indeed manifold; it requires investments in computer infrastructure, teacher training, increasing the support staff etc. There is some debate on the role of industry in providing money to realize educational changes. Should industry fund educational reform or should it remain the province of government as it has in the past ?

3. Educational software in Europe : food for thought.

Teachers are eager to use multimedia software and are in particular interested in having some control over the technology used. It became obvious that they wanted to be involved at the grassroots level and empowered with tools to truly integrate technology in their classrooms. They expressed a strong desire of being in control of enhancing their teaching by technology and doing so by familiarizing themselves with authoring systems which would allow them to create their own teaching materials. In addition, teachers strongly value the communication power that computers embody. They feel that would facilitate the creation of a much needed teacher/learner community. Networking was overwhelmingly considered a positive evolution; students, teachers and principals felt that they could reach out to the world. Vice versa internet and WWW bring the world into the classroom.

> "*There is no other way forward - there should not be an insular approach to education, with schools working in inward moving spirals but in outward ones, pooling resources and sharing expertise...The very nature of communications today (e.g. The Internet) makes this the case, and it is up to the educationalists to ensure there are no dangers to this.*
>
> Secondary teacher, UK

Both publishers and teachers are willing to cooperate from an early stage in developing good quality software, bringing in their own particular expertise. Moreover, the government needs to take some initiatives to inject life into the educational software market. An issue which remains to be tackled at the European level is the problem of language barriers. There is a need for translation in spite of difficulties of translating 'cultural-related' content and to transpose software to a different cultural environment.

VI. Towards Partnerships

Until recently, education policy has been mainly the province of government, particularly regarding funding issues. From the above, it becomes apparent that both public and private sector share a similar vision on the educational process of tomorrow using information technology and aim at similar objectives such as increasing the knowledge level of European citizens and to protect Europe's competitiveness in the global market. However, cooperation between the varied constituents will call for an open mindedness regarding cultural based beliefs (e.g. should industry fund schooling). Such issues will have to be solved. If schools are truly to enter the information society, it seems crucial to move towards partnerships at many levels; e.g. between education and business, between schools and educational software providers, and between schools, teachers and learners. Such powerful combination can lead to a real learning community and be a catalyst for a positive change in education.

Abstract: *The article describes the authors' experience in the construction of geographic interfaces for educational hypermedia applications. In systems based on the metaphor of maps different navigation paths are possible. The article presents the principal of these and highlights the nature of the tools (general primitives) that enable the student to exploit the map collection as an ontologically well-founded system for the retrieval and study of geo-referenced data. It shows that hypermedia applications of this kind require specialized and abstract data models that are difficult to implement in the hypermedia systems currently available on the market. It also shows that these applications are different from usual 'display oriented' hypermedia applications. The article then describes a number of prototype navigation tools obtained by extending the functions of a hypermedia system currently on the market.*

Introduction

Our interest in extending the functions of hypermedia systems to manage geo-referenced data originated in a project to develop hypertext teaching materials. During this project, a number of prototype hypermedia systems were constructed, representing problem classes judged of major interest. Some of the solutions adopted suggested that works traditionally described as reference materials (atlases, glossaries, concordances, etc.) are, metaphorically, *gates* among the corpora of traditionally distinct disciplines. If these works are transformed into electronic hypermedia systems, and if this operation is performed non-trivially, gates normally closed because of the natural tendency to specialization among scholars are thrown open. The results presented here arise from this conviction and concern development of a prototype hypermedia atlas. From a technological point of view, literary works are structurally different from a collection of nodes and links. Bieber & Kacmar [Bieber & Kacmar 95] have recently stressed this difference, distinguishing between display-oriented and computational-oriented hypertexts. Bieber and Kacmar give the example of a Geographic Information System (i.e. an electronic version of an atlas) to show that a user employing a tool of this kind is involved mainly in investigation of the reality represented in the atlas itself. In other words, the users of a GIS often perform actions which require calculations based on the geo-referenced data that constitute the system knowledge.

Three options are available in computational-oriented applications. The first is an expansion of hypertext systems (typically display-oriented) to include computational aspects, as in [Halasz 88] [Schnase & Leggett 89].The second is to extend the functions of a computational-oriented system to include hypertext technologies, and this is the road pursued in [Bieber & Kacmar 95]. The last option regards the availability of Open Hypermedia System (OHMS). In our opinion, a Computational Oriented system should interact with a Display Oriented system through a common protocol. The reader can find in [Østerbye & Wiil 96] a method for the classification of the opening degree of a hypermedia system. This paper includes specific bibliographical references to the most important approaches of Open hypermedia systems. In [Wiil & Leggett 96], the authors present their approach for a OHMS and discuss seven requisites that an open hypertext should have: *scalability, openess, distribution, heterogeneity, interoperability, extensibility, computation*. When hypertext technologies are used for didactic purposes, the option of expanding the functions of a computational-oriented system is not appealing. In fact, an educational course supported by hypertext technologies frequently involves the use of more than one computational-oriented package. Consider, for example, a university course in statistical data analysis. A hypertext containing the text of the lessons will probably be used, but almost certainly also a data analysis package like SAS™ or SPSS™, a DBMS, a symbolic calculation program like Mathematica™ or MATLAB™, a G.I.S. like MapInfo™ for the spatial representation of phenomena, and so on. To imagine that all these products include hypertext extensions, and further that these extensions are compatible, is somewhat unrealistic at the present time. Moreover, the problems raised by the introduction of hypertext primitives into applications using geographic metaphors are far from being resolved. In fact, the relation between geographical components and other components of a hypermedia can be interpreted in different ways (which we here call 'routes', see [The potential roles of geographical maps in a hypertext]).

A "route" is an interpretation of the relations between maps, and between maps and other components of a hypermedia. It discriminate the use of the relation rather than the relation itself. These new routes change the requisites at the basis of a hypertext system, as well as those normally regarded as valid for GIS. Hypertext systems are only the most evident aspect of a different manner of conceiving the use of calculating apparatus to produce new knowledge. They are therefore destined to interact with a large number of generalized software if they have to be the technological basis for a new literature. At the same time computational-oriented systems must be redesigned to allow fruitful interaction with a literary sphere now irremediably changed. As regard as the last option, i.e. the use of a OHMS, in our interpretation of the term "open" both computational and display-oriented systems should be modified to communicate among them through a common protocol. On the other hand, it is commonly believed that the computational ability is one of the requirements of a OHMS [Wiil & Leggett 96]. In this way, these approaches follow the first option as well, i.e. expanding HT systems to include computational aspects. We therefore chose to extend the functions of a commercially available hypertext system by adding primitives to it in order to handle maps, rather than adding hypertext functions to a commercially available GIS. We are convinced, in fact, that a GIS capable of performing hypertext functions has little similarity with the current standard of these systems.

In the paper, section 1 discusses some of the problems involved in the construction of geographic interfaces in a hypermedia environment, and section 2 presents some examples of interfaces developed in our prototypes. The other sections of the complete paper are on the CD-version of the proceedings.

1. The potential roles of geographical maps in a hypertext

A geographical map in a HT can potentially perform several roles, and a HT system which incorporates primitives for the geographic representation of maps must furnish primitive functions for these various roles. If one considers a map to be an aggregate object called ***map*** which can be visualized in a more general object called ***atlas page***, then the object ***atlas*** composed of ***atlas pages*** must be able to perform one or more roles. This entails that a map must behave differently according to the role that a reader and/or author attributes to it. For the sake of simplicity, we may distinguish between nodes that describe geo-referenced entities (**GRE**), and nodes that instead provide a graphical representation of geographical space and which we simply call **Maps**. There is, moreover, a third class of nodes which represent the statistical features of the **GRE**s in aggregate form. These nodes we shall call **Indices**.

Since a geographical map is a well-known approach to spatial phenomena, it comes as no surprise that many hypertexts have adopted this metaphor to facilitate navigation. One of the first applications was the Glasgow Online project [Baird & Percival 89], which used the map of the city of Glasgow to provide access to tourist information. But geographical metaphors are also to be found in 'historical' hypertexts in the broad sense which make frequent use of maps as navigation devices and/or for the dynamic visualization of historical phenomena.

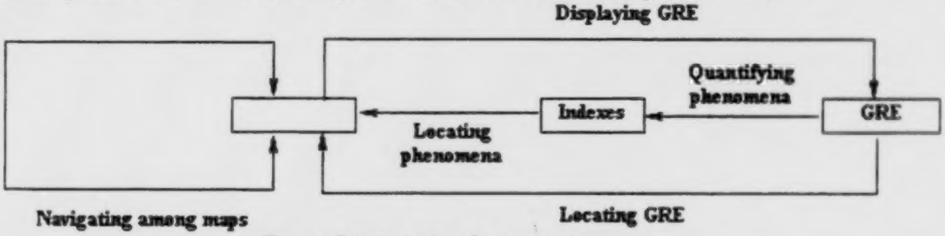

Figure 1 Principal roles of a map in a hypertext

Despite these points of 'metaphorical' contact, the convergence between **GIS** and **HTS** has not gone much beyond the use of maps as access to geo-referenced data in **HTS,** and the use of technologies based on the concept of 'object' in the construction of GIS (a necessary but not sufficient condition for the handling of multimedia data). The principal roles of a map in a HT are set out in [Fig.1], which shows the principal navigation routes between geographical entities and maps. The diagram will serve as a guide for the argument developed in this section.

1.1. Navigating among maps

If a system of electronic maps is available, it is relatively simple to construct functions which make it possible to navigate among them. Navigation within a system of maps can take place in many ways, but three of them seem to be of principal importance: moving along compass routes, changing the scale, changing the projection. We shall briefly discuss the first two, since the third is less frequently used.

1.1.1. Moving along a compass card.

To obtain this result, actions in the interface must be interpreted as requests to move in a geographical space. If the geographical space has been quantized into a finite set of maps, each of which is a node of the hypertext, and if a network of links consisting of circular lists like those shown in [Fig.2] is constructed among these maps, then movement along one of the eight principal compass directions is relatively easily achieved with commercially available HT systems. The structure of the links shown in [Fig.3] allows the implementation of what [Van Dyke Parunak 89] calls a "direction navigational strategy". The resulting topology of the links among different parts of a map is a ordered hypercube. Navigation among fragments of maps comes about by interpreting movements of the cursor {up, up_right, right, down_right, down, down_left, left, up_left} as requests to move to fragments of the map located respectively to the {north, north_east, east, south_east, south, south_west, west, north_west}.

1.1.2. Changing the scale

In many situations a request is made to pass from one map to another one of greater or lesser detail. For example, on a hypermedia interface showing aggregate statistics at a national, regional, provincial and municipal level, a hierarchical path must be constructed which enables easy passage from a map in which space is divided into countries to another map in which a country's territory is shown as the aggregate of regions, and so on. To perform these actions, it is possible to interpret a click on the left mouse button as a request to move to a level of greater detail, or alternatively a click on the right button as a request to shift to a broader geographical context. In both cases what is being requested is a change of scale with the relative increase/decrease of detail.

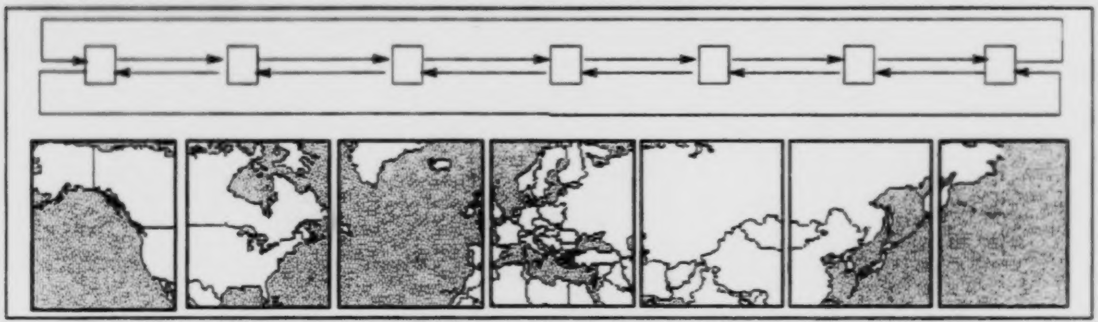

Figure 2 East and West routes along parallel directions (above) with corresponding geographic sub-part (below)

However, performing this kind of navigation with currently available hypertext systems is difficult. In order to change the scale, in fact, it is necessary to redesign the objects that constitute the map, recalculating the positions of all the vertices of the elementary objects, and hypertext systems do not possess sufficient calculation capacity to do this. Moreover, as said, a change of scale also involves the concealment or display of details. In navigation systems such as that described, disorientation may be provoked by loss of context (especially with highly detailed maps). For this reason, the automatic iconization of contexts is advisable.

1.2. Maps as indices for direct access to hypertext fragments

This is the usual way in which maps are handled in hypertexts. In this case, a map is a special fragment in which map symbols (dots, lines, regions) act as points of access to other fragments of the hypertext. Clicking the left mouse button on one component of the map is interpreted by the interface as a request to move from a geographical fragment to a non-geographical one. Thus maps can be used to construct a graphical index where a geographical entity corresponds metaphorically to an entry in an index of non-geographical fragments. As will be discussed in more detail in section [Extending the concept of geographical entity selection: an example], if a system of maps is used as an index for a collection of geo-referenced data, then the navigation actions and choices among maps can be interpreted as selections from the collection of geo-referenced data.

1.3. Maps as instruments for the visualization of the spatial location of events

The relationship between the geographical representations constituting an electronic map on the one hand, and heterogeneous fragments of data on the other, can also be investigated in the reverse direction. If while using a generic non-geographical fragment one comes across a toponymical reference, or a reference that can be made to correspond to a toponomastic reference, a hypertext should permit the visualization of the corresponding map. This is apparently trivial: if we assume for simplicity's sake that the toponym is a string of text, then activating the link defined on the toponym is equivalent to a request to jump to the geographical fragment whose name is equivalent to the toponym string.

On closer examination, however, the question is more complex. Alfred Korzybski [Korzbysky 41] warns us that: "A map is not the territory and the name is not the thing designated". For example, to what map must one jump when the link associated with the string '*Mediterranean*' is activated? Consider the following alternatives: (a)pass to the political map showing the borders of all countries with coastlines on the Mediterranean; (b) pass to a nautical map of the Mediterranean; (c) pass to a map showing the spatial extension of climate defined 'Mediterranean' in the Mediterranean basin; (d) ecc.

The question complicates further if maps have a historical dimension. For example, the string 'land of Otranto' does not designate the present-day geographical extension of the town of Otranto (Lecce, Italy).

1.4. Maps as instruments for the visualization of phenomena

All maps are thematic maps. From a technical point of view, a map is the representation of one or more themes on a reference system. Some of these themes can be considered basic (the boundaries of administrative units, orography, the road network, etc.) and can therefore be somehow preconstructed on a geographical interface, thereby creating what in jargon is called a 'white map'. A white map is nothing but a map in black and white - that is, a device on which different colours can be used to express the geographical extension of a particular phenomenon. This process gives rise to a new map with a new theme. For example, a geologist, on completion of his survey of a portion of territory, can compile a geological map using different colours for the different portions of territory on which particular rock formations are to be found. In an automatic processing environment, when collections of geo-referenced data are available, it is possible to produce thematic maps automatically - but under certain minimal conditions: (a) - the elementary components of a geographical representation (lines, polygons, dots) must be directly addressable; (b) the record of the values of the phenomenon to be described by a thematic map must be geo-referenced; (c) there must be a 1:1 cardinality relation between the graphic objects that constitute the map and the records; (d) there must be a finite collection of logical forms like those represented by the following threefold expression: <value_threshold α, value_threshold β, indicator_visual x>. Where **threshold value α** and **_threshold value β** are two numerical values which define an interval, and **_indicator_visual** x identifies a graphic sign, for example a colour. Verification of the formula value_indicator J **Between** [value_threshold α, value_threshold β] for all the records of a database enables a new map to be drawn.

A hypertext intended to be 'open' to readers must allow them to construct their own thematic maps starting from portions of archives containing base statistical indicators. Moreover, this approach is computationally more economical than the storage of numerous thematic maps as preconstructed images.

2 The topological relations among geographical entities

Since in a hypertext system the intention is to use primitives in order to interact dynamically with the maps, a model of the topological relations among the base geographical entities is needed. While developing our prototypes, we experimented with a model of the relations among geographical entities set out in [Egenhofer et al. 91]. This model will only be briefly summarized here, and the interested reader is referred to the original texts [Egenhofer et al. 89],[Egenhofer et al 93], [Egenhofer et al 94].

A topological relation between two geographical entities can be defined as a relation that establishes a connection between the two entities on the basis of their respective geometrical properties. In this model, the formal definitions of the objects (entities) and their relations are based on the point-set approach, where the entities are the sets and the points are components of these sets. The subjects of the relations are the points, lines and regions commonly used in GIS, and the topological space is R**2. All types of entity are closed sets (therefore every entity contains all its points of accumulation) and they are coherent - that is, they are not the union of two separate entities. A primitive function DIM(S) is constructed where S is a set of points. When this function is applied to a set of points, it restores the size of the set. If the set is composed of entities of different sizes, the maximum size is restored. DIM(S) coincides with the empty set if S is empty; DIM(S) is 0 if S contains at least one point but no lines and no regions. DIM(S) is 1 if S contains at least one line but no regions; DIM(S) is 2 if S contains at least one region. On this basis two further functions are defined: the primitive BORDER(S) and INNER(S). By compounding these two primitive functions it is possible to classify the relations among geographical entities. This classification is based on the four possible intersections between the primitives BORDER(S) and INNER(S). Not all the theoretically possible relations are meaningful: some of them, in fact, yield an empty set. For example, in the case of two regions the effectively possible relations are six in number: disjunction, inclusion, tangency, equality, coverage and superimposition. [Tab 1] gives the results for all the other possible relations. In conclusion, Egenhofer's model envisages the construction of five primitives for the purpose of investigating the relations between two geographical entities whatever, i.e. the primitives: touch; disjoint; in; cross; overlap.

Entity	Entity	N. of possible relations
Region	Region	6
Region	Line	17
Region	Point	3
Line	Line	18
Line	Point	3
Point	Point	2

Table 1

2.1 Extending the concept of geographical entity selection: an example

In this section we shall provide an example of functions constructed in our prototypes following the adoption of an abstract model of the geographical objects in the interface space. In particular, we shall show the effect on navigation of extending the concept of choosing an object on the interface. If a map is associated with a table of data, then the operation of selecting an element of the map can be interpreted as selecting from the table of data: see for, example, [Fig.3a] [Fig.3b] [Fig.3c]. Selection of a geographical object is a function that can be simply obtained by associating it with a state of the map and with an action using the mouse. Possible actions are generally of two types. The first type comprises 'point & click' actions which consist in pointing the mouse at a theme and clicking. This type of action is usually performed when the user wishes to select individual objects. If several objects are to be selected, other actions must be added to the sequence, for example making a click while pressing one of the keys on the keyboard.

Figure3a The selection on the map Figure3b The coryspondent query Figure3c The resulting table

The second type of action consists in the activation of a sort of virtual window. Clicking on a point on the screen activates the window, and until the next click every movement of the mouse changes the border of the window. Once the virtual window has been fixed by the second click, it is transformed into an elastic structure which forms only around objects wholly contained within the window, and these constitute the selection made. This type of action is usually performed when one wishes to rapidly select several contiguous objects.

However simple it may be to perform the selection operation on the interface, it becomes a very powerful operator on the basis of data associated with the interface's geographical objects [Guting et al.93]. In the DBMS back-end space, in fact, it is interpretable as a selection of all the records of non-geographical data whose identifier corresponds to the identifier of the objects selected on the graphical interface. For example, suppose that we are navigating among maps until we reach the fragment containing the map of southern Italy in 79 BC and then select the city of Pompeii. A selection on the interface may correspond to selecting all the records regarding objects excavated at Pompeii. Note that, as said, also the operation of navigating among the maps can be interpreted as a dynamic selection among the records of the data base. In fact, choosing the map of southern Italy entails selecting all the rows concerning archeological findings in southern Italy; choosing the map for 79 BC restricts the search to those dating to 79 BC.

If primitives are implemented which are able to calculate the status of the topological relations among the graphical objects representing geographical entities on the interface, the selection operations performable on the interface can easily be extended. In our prototypes, in fact, virtual window-type selection actions were modified by adding two new forms of selection, called *partial selection* and *external selection*. In partial selection all the objects covered by the virtual window are selected, even if they do not lie wholly within it.

In external selection, instead, all the objects lying outside the virtual window are selected. As regards implementation, partial selection is obtained by verifying which geographical entities respond positively to the primitive 'in' or to the primitive 'cross' with the region represented by the virtual window. In external selection, the primitive used is instead 'disjoint'. Also these actions are interpretable in the back-end as queries to the database

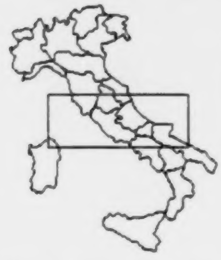

Figure 4a Selection windows

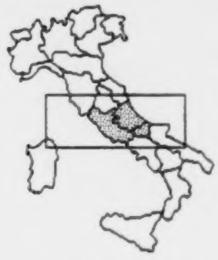

Figure 4b Inner selection

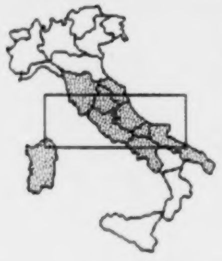

Figure 4c Partial Selection

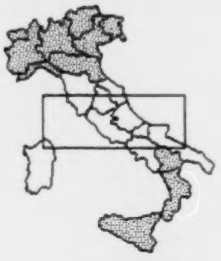

Figure 4d External Selection

. In the above example, the external selection amounts to selecting all the records concerning archaeological discoveries in southern Italy datable to 79 BC but not found at Pompeii, while partial selection can be used to select objects found in adjoining areas as well.

Once the selection method has been chosen, the reader uses the virtual window. The action of fixing the borders of the window sends a query to the back-end primitives, which calculate the topological relations among the objects present on the map and the coordinates of the virtual window. The result of this calculation is a list of objects that satisfy the topological relation and that is used by the front-end to evidence the result. Simultaneously, the list of values identifying the objects selected can be used as a condition in OR to trigger a new back-end process consisting in the selection of occurrences from the database. Referring to [Fig.4], in which all the Italian regions are stored in a database with their names, the three selection operations are expressed by the following simple SQL queries.

Inner Selection

SELECT * **FROM** GRE **WHERE** Region="Lazio" OR "Abruzzo" OR "Molise"

Partial Selection

SELECT * FROM GRE **WHERE** Region="Tuscania" OR "Lazio" OR "Abruzzo" OR "Molise" OR "Umbria" OR "Marche" OR "Campania" OR "Puglie" OR "Sardinia"

External Selection

SELECT * FROM GRE **WHERE** Region NOT = ("Tuscania" AND "Lazio" AND "Abruzzo" AND "Molise" AND "Umbria" AND "Marche" AND "Campania" AND "Puglie" AND "Sardinia")

The opportunity offered by the data model of calculating topological relations among geometric representations enables actions to be performed in the interface to obtain objects of different degrees of abstractness. In fact, the relations can be calculated on the basis of only one of the graphical objects that make up a map. In other words, once an object has been selected, all the other objects that stand in a specific relation to it can be straightforwardly obtained. In some cases, the set obtained has a specific meaning that depends on the specialization of the geometric entities considered. For instance, if the calculation is restricted only to river-lines (i.e. the broken lines that represent rivers), once the river Colorado has been selected, it is easy to show its tributaries. In fact the Colorado's tributaries are all and only the river-lines tangential on a single point with the line identified by "Colorado". The calculation can be performed recursively with all the tributaries of the Colorado until all the watercourses that constitute the Colorado basin have been evidenced. In this case, 'basin' is an abstract entity obtained as an aggregation, on the condition that all the component lines are directly or indirectly tributaries of a generic river.

3. Conclusions.

From our experiments with hypertexts, we are convinced that it is necessary to reconsider the technology employed to handle geographical data. The development of hypertext applications for large corpora of information means that extending HTS performance becomes increasingly urgent. In other words, the ability of these systems to connect heterogeneous data fragments together also highlights their limitations. We believe that much work will have to be done in the future if HT systems are to become efficient devices for the production of cultural artifacts. If this does not happen, the great potential of these technologies will be frustrated. The outcome will be, not the progress of knowledge, but its trivialization as evidenced by so many of the products currently on the market.

Student CD-ROM Portfolios

Terry Corwin, Associate Professor, Director of Instructional Technology, Valley City State University, USA, corwin@badlands.nodak.edu

Sara Hagen, Lecturer, Department of Music, Valley City State University, USA, sahagen@badlands.nodak.edu

Abstract: The paper describes the diffusion of an innovation, CD-ROM portfolios, into the curriculum of a laptop university over a six year period. A Title III Grant provides the money for the project. During the completion of each student's degree requirements, the student saves projects which demonstrate the abilities expected by the university. Prior to graduation, each student organizes the portfolio and burns a CD-ROM for use by prospective employers. The process of diffusion is discussed as well as hardware and software choices. An example of a Music Education project to be used as part of the portfolio is included.

Project Background

Valley City State University is a campus of about 1,000 students. Eighty percent of its students major in Education or Business. It became a notebook computer campus in the Fall of 1996 when all full-time students were issued notebooks upon registration. The faculty received their notebooks and appropriate training in February of 1996. These realities make the ambitiousness of the CD-ROM Portfolio project more lucid.

The project, to use portfolio assessment as a tool in the Valley City State University Curricula and from it allow students to create CD-ROM portfolios prior to graduation, became visible on the campus in November of 1995 with the hiring of a Director of Instructional Technology. The following two months were spent orientating the campus to the project as well as remodeling the multimedia area for the project and planning for the purchase of appropriate equipment. Presentations concerning the grant were made to all entities at the university including staff, administration, faculty, and the Portfolio Learning Team. (the Learning Team consisted of 10 faculty and 14 students who volunteered to learn about the CD-ROM creation and then mentor a peer in the Fall of 96) The Director received training during this period on the architecture of Windows 95 and in-depth training on the operating system since this would be the operating system in the multimedia lab.

During the first two months of the new year final equipment decisions were made, bids were taken from venders and leasing companies were contacted. The hardware for the Portfolio multimedia lab was obtained on a capital lease over three years. Through the leasing process the equipment money authorized in the grant for the first three years could be put to use in the first year. The lab consisted of five multimedia stations.

Also during this period all faculty were issued notebook computers in preparation for Fall 96 semester when all members of the student body would also receive a notebook computer upon registration. Immediate training for the faculty began concerning the care and management, the hardware, the software and the communication systems available with the notebook. Special training for the Portfolio Learning Team on the advanced PowerPoint skills was also completed. This was needed because the plan, at least initially, is to use PowerPoint as the authoring software for the CD-ROM Portfolios. Although PowerPoint has weaknesses as an authoring software, its strengths are its availability to all faculty and students on the campus, its existence on both PC and Mac platforms and its uses in other types of academic projects.

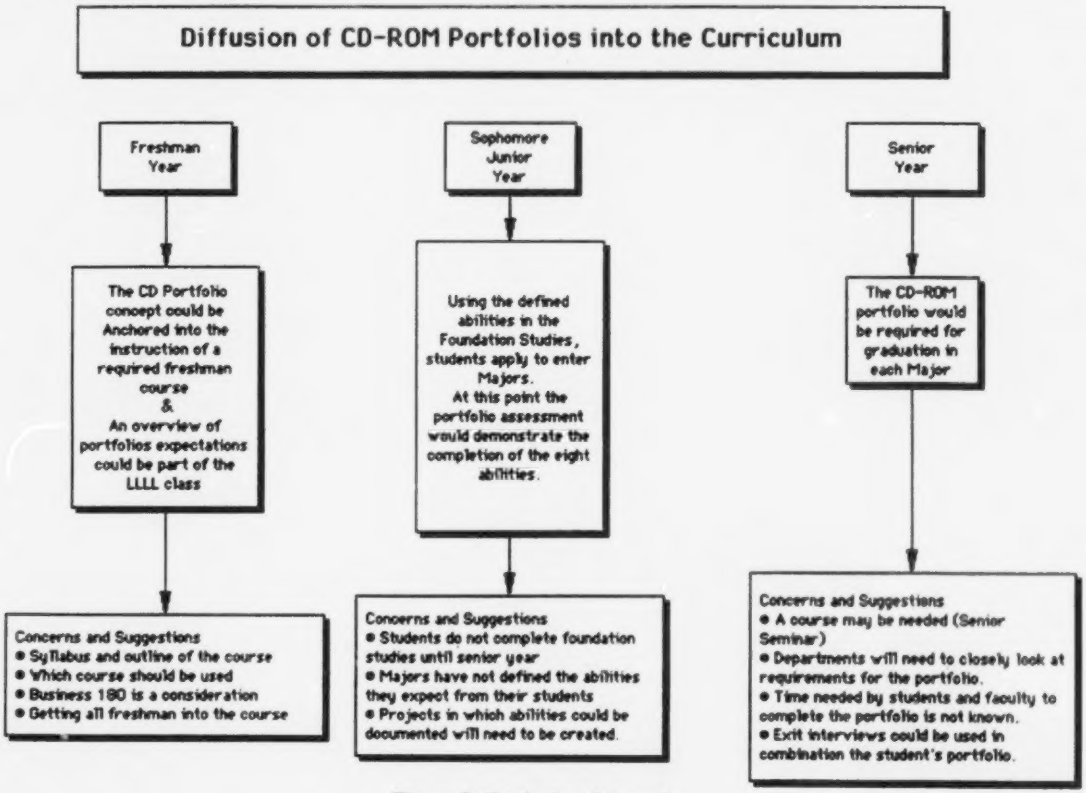
The Learning Team, composed of ten faculty members was expanded to include fourteen students. Learning Team meetings focused on portfolio use in the classroom setting. Faculty on campus who had used portfolio assessment were invited to join the discussions. Outside consultants were considered and contacted for future contributions. Finally, a three ring binder was created for each Learning Team member containing information on portfolio issues and on each of the necessary softwares. The material in the binder was used as a resource, and in the mentoring process for the Fall 96 Learning Team.

During the final months of the 1996 school year, March-May, the Learning Team's discussions focused on internalizing the use of portfolios as part of the curriculum. The process began with discussions of the newly established foundation studies abilities. The portfolio process is seen as a way of allowing students to show competence levels in the eight abilities identified. The Learning Team also conducted discussions with K-12 administrators and business executives concerning the use of the CD-ROM by future employers of Valley City State graduates.

Also during these months the campus network was completed and remodeling of 16 multimedia rooms was planned. These rooms include hardware for computer and video projection as well as network, intranet, Internet and electrical connections for student computers. The Title III room remodeling was completed, the new equipment arrived and was prepared for use.

Faculty/student Learning Team members received training in each of the skills needed to create a CD-ROM portfolio. Each training included a "How To" resource sheet for inclusion in the Learning Team binders. Each Team member completed a project showcasing the skills acquired during the training sessions. Summer stipend projects were outlined by each faculty Team member

Prior to the end of the Spring semester, new learning team members for Fall semester were identified and a rough draft of a plan for informing the freshman class about portfolio expectation was completed. A meeting was held with the Chairs of all of the academic divisions on the campus. At the meeting a flow chart [Fig. I], created by the Learning Team, for internalizing the (CD-ROM) Portfolio concept into the curriculum over the next four years was discussed.



Diffusion of CD-ROM Portfolios into the Curriculum
Freshman Year
Sophomore Junior Year
Senior Year
The CD Portfolio concept could be Anchored into the instruction of a required freshman course & An overview of portfolios expectations could be part of the LLLL class
Using the defined abilities in the Foundation Studies, students apply to enter Majors. At this point the portfolio assessment would demonstrate the completion of the eight abilities.
The CD-ROM portfolio would be required for graduation in each Major
Concerns and Suggestions
• Syllabus and outline of the course
• Which course should be used
• Business 180 is a consideration
• Getting all freshman into the course
Concerns and Suggestions
• Students do not complete foundation studies until senior year
• Majors have not defined the abilities they expect from their students
• Projects in which abilities could be documented will need to be created.
Concerns and Suggestions
• A course may be needed (Senior Seminar)
• Departments will need to closely look at requirements for the portfolio.
• Time needed by students and faculty to complete the portfolio is not known.
• Exit interviews could be used in combination the student's portfolio.

Figure I: Curriculum Integration

BEST COPY AVAILABLE

A priority during the summer months was to make graphic recording of events more available to the campus in general. Toward this end, several pieces of graphic recording hardware were purchased (digital camera, Snappy and Quickcam). These are available for faculty and student check out. Also a Polaroid Educational Workshop is scheduled for the coming school year. This workshop gives a Polaroid camera to each participant.

During the week prior to the 96-97 contract year optional workshops for faculty were held. They included PowerPoint, Web Page Development, Use of Network, and Groupwise E-mail. Faculty in-service included sessions on Portfolio use in the classroom and an overview of database software to be used in tracking the abilities required as part of the CD-ROM portfolios.

By September 30th Summer projects will be completed and given to the Title III Director. Each will be accompanied by a written summary and digital results where applicable. One of the summer projects involved the creating of a Digital Template for the portfolio. That template will be used to complete the first sample portfolio on CD-ROM. It is also being used as part of a presentation to each Freshman orientation group on campus.

Priority I: Integrating Portfolios into the Curriculum

The use of the hardware and software to created the portfolios is certainly a concern, however, integration the portfolio concept into the students four year education created a larger road block. The visual form [Fig. I], explains the expectations developed by the Learning Team during its first year of existence. The plan includes:

1. exposing freshmen to the CD-ROM portfolio concept new student orientation courses during the first few weeks of their freshman year.

2. using the portfolio concept as an anchor for the software in a freshman level technology course

3. creating a portfolio at the completion of Foundation Studies courses. It is to be presented to faculty in the student's major curricular area the. This portfolio will illustrate the student's level of ability in each of the eight objectives.

4. Divisions/Departments requiring a completed portfolio as a graduation requirement for the major area. The portfolio may be tied to a course or an exit interview.

Priority II: Ability Based Foundation Studies

Since 1993 Valley City State has begun to rethink the foundation studies objectives. The new direction included, expressing objectives in a more measurable form, stating clearly the expectations connected to the objectives and a clear understanding of the student expectations connected with the objectives. The portfolio would be central to involving the student in the assessment of the process. It also allows for a very visible format in which the student can show growth.

The result of these changes is a list of eight abilities which reflect the Foundation Studies objectives in a more assessable format. The abilities follow.

Communication
Effective Citizenship
Aesthetic Responsiveness
Technology
Problem Solving and Decision Making
Collaboration
Global Perspective
Wellness

Closely tied to Valley City State's expectations concerning the recording of student ability levels and the creating portfolios is the notebook initiative. Every full time student and faculty member on the campus has an IBM Think Pad. The notebooks allow student to create and save materials on there own hard drive. The campus network also allows for fairly simple movement of large files from computer to computer. Both, make the saving of materials and creation of the CD feasible for a large number of students. The graphic [Fig. II] is a visual representation of the strategy.

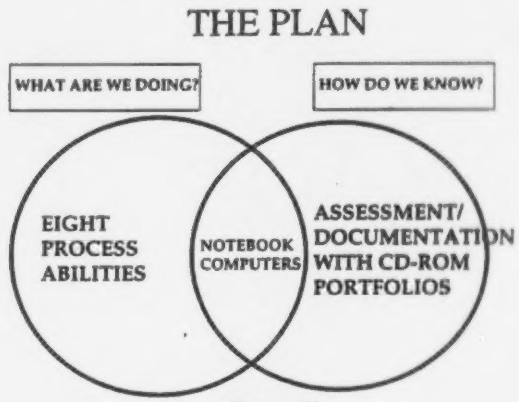


Figure II

The integration of the portfolio concept on the campus involves a faculty/student Learning Team.. An effort was also made to use experience and expertise concerning portfolios which already existed on the campus. Faculty development funds were used to encourage individuals to share such expertise. One such workshop by a faculty member spawn the following portfolio projects by faculty in several divisions.

- Physical Education - Developed a five to ten minute videotape on a first aid skill. Student groups created the video tapes. Portions of the tape will be digitized and used to show the students proficiency in the first aid skill.

- Elementary Education - Students developed personal class portfolios using the software PowerPoint. The portfolio will demonstrate what was learned by the student during the course.

- Humanities (Visual Art Component) - The class is producing projects in which the students are making mock presentations to museum boards. The presentation asks the Board to consider a painting for possible acquisition. Each student group then makes a presentation illustrating what they have learned and this is videotaped.

Background of the Student Portfolio Project

This pilot project for interdisciplinary teaching among the public school fine arts departments, the Valley City State University (VCSU) music department, and the Valley City community began in the spring of 1996 when all the cooperating institutions gathered representatives to write a grant to US West for the funding of a dream. The dream was to create a project based in real life which would allow young people opportunities to work together to create original opera. The theme chosen for the project was "Coming of Age in Valley City" with the aid of the institutions working cooperatively together. The dream was to have eighth grade students write lyrics, compose music, create artwork, and produce an original opera which was completely student-driven. In order for these young students to produce such a large project, technology and mentoring from older students and adults was included in the plan. "Coming of age" also meant discovering the senior citizens in our community and thus they were also included through an ongoing federally funded program called SAGA (Spanning Age Groups with Artifacts).

The grant was won in mid September, 1996 for $16,000.00. The original budget was $80,000, so many of the needs were not met. However, our priority was a six workstation lab which was put in place in the junior high school. Each workstation had a PowerMac 5260 with CD ROM drives, 8mg RAM, and 500 mg hard drives.

The Yamaha PSR320 electronic piano was chosen for its price and flexibility. Each keyboard is equipped with a dual headphone system so that two students can work together. The onboard sequencer/recorder allowed many students the ability to experiment and capture their sounds without having to remember everything they did. This information was then dumped into the notation software, Overture. The students could then edit their work and produce almost music publisher quality "sheet music." The keyboards and computers were connected with Altech MIDI (Musical Instrument Digital Interface) translators and 5-pin MIDI cables. In addition, all of the computers were networked with Appletalk to a laser printer. Finally, one workstation was designed as a teacher presentation station in a Wenger cabinet which was connected to a Zenith TV monitor. Future plans for the lab include a Yamaha Clavinova (or several) and a piano lab networked teacher station which will allow students to be grouped, allow for the teacher to listen in on the work in progress, and provide a communication system among the students in the lab.

Valley City Public School shares two music teachers with VCSU and has served as a "lab school" for the pre-service teachers being trained at the university. This project allowed for two VCSU music students to earn a stipend of $150.00 per semester (essentially paying the expense of the course) and one credit per semester as they worked with the eighth graders. The class was titled Music Technology Internship in the Junior High School. The course provided for two semesters of mentoring and teaching for two hours per week. The college students were trained on the software and hardware and had practice sessions on composition activities during the first few weeks of the semester. The MIDI lab was put in place in late September with training sessions for the eighth graders beginning the following week. Following an orientation period, the VCSU students led activities in composition which eventually became the basis for the songs used in the opera. The two institutions also share an art teacher who worked with students to prepare the backdrops for the opera. The art department also worked with SAGA to produce a mural based upon old photographs of Valley City which was painted on the side of the administration building which stands on Central Avenue.

As the VCSU music students worked with the eighth graders, they collected various pieces of materials which would document their work in progress. These materials were collected as video, audio, MIDI files, word processed documents describing their work, lesson plans, etc. The materials were gathered into the portfolio which you will see on the CD ROM which was produced as a result.

Student Learning Goals as Described in the Grant.

Eighth Graders

1. Interdisciplinary. Students will understand the relationship between literature, music, and the visual arts. Students will learn to work cooperatively with their classmates, with their instructors, with college students, and with community volunteers to produce an interdisciplinary performance around a chosen theme.

2. Technology. Students will learn to use technology to enhance the creative process in writing, music composition, art, and presentation.

3. English. Students will learn the elements of a short story and drama and use these elements to write a script. Students will learn to write dialogue and how motivation plays a major part in the dialogue. Students will learn stage presentation, blocking, and vocal projection.

4. Music. Students will compose short pieces within specified guidelines, using MIDI technology, assisted by college music education students. Students will demonstrate an understanding of how music enhances the plot and dialogue in the lyrical theater.

5. Visual arts. Students will learn how to design and paint a large mural. Students will learn to document the process using digital cameras. Students will learn to design a set for the music production using slide projectors to present a documentary visual display.

College Students

1. Students will learn basic music technology skills such as setting up and operating the MIDI stations. Students will design lessons on MIDI and practice their teaching skills teaching eighth graders. Students will utilize different strategies in aiding the creative process of composition, providing guidance in successful harmonizations, and teach mini-lessons on tune-building, i.e., sequence, repetition, and intervals.

2. Students will develop a Compact Disk, using the electronic portfolio development process being piloted at VCSU, containing footage and descriptions of their experience working with junior high students for their professional portfolio.

Acknowledgments

It is important to acknowledge the entire faculty at Valley City State University. They have not only adopted this project but have enriched it by attending numerous workshops and help sessions; and expanded it with new and innovative ideas. A special appreciation is also extended to the faculty and administration who wrote and submitted the Title III Grant that made the project possible.

Integration of Multidatabase Technology with Multimedia Application Authoring Tools

Katherine Curtis
Steven R. Lerman
Center for Educational Computing Initiatives
Massachusetts Institute of Technology
Cambridge, MA 02139 U.S.A.
{kate, lerman}@ceci.mit.edu

Abstract: As the complexities of multimedia applications increase, large amounts of media data are required for each application. A case is made for the inclusion of database support in application authoring environments to aid both media management and access. A virtual database model is proposed and implemented for the AthenaMuse2™ application authoring tool. The virtual database provides the author with a standard object-oriented interface to all the major types of database system. The virtual database is responsible for all data model translation issues that arise. A variety of example applications are described which emphasize the flexibility and usefulness of the model. Extensions to the model, for example application object storage, are proposed.

1 Introduction

Improvements in storage technologies and processing speeds have led to the development of a new generation of multimedia educational and entertainment software, where each application may incorporate thousands of different media elements such as text, images, audio, video and graphics. The majority of software development tools force the application author to encode the media either directly (for example, by typing in the text to be displayed) or indirectly by specifying the file name of the media that is to be displayed. This process has two distinct disadvantages. First, performing modifications to the data requires access to the authoring tool, putting such capabilities beyond the reach of the user. Even if the external data files are accessible, there is no easy way to identify which data element can be found in which file. Second, using only the file system to keep track of a large number of media elements during the application development process becomes very cumbersome. Finding the name of a file corresponding to a particular piece of data can involve searching through large amounts of application code and accidentally moving or deleting a file will result in a broken application. Development environments which incorporate tools for managing and searching media are needed.

The addition of database facilities to the authoring environment provides a centralized mechanism through which data can be stored, accessed, modified and deleted in an orderly fashion. A database access language can be used to specify data independently of the file system and other environment variables. Media objects can be modified in the database and these modifications realized in the application, without altering the application code. Database systems are specifically designed for tasks such as data entry, deletion or modification and provide appropriate interfaces for these functions. Once all data belonging to a particular application is stored in a centralized location, such as a database, it becomes much simpler to protect against accidental deletion and to move or copy the data as a single unit. Database systems can provide extensive facilities for data searching and querying that would not normally be available to an application. If selective data is required by an application it can be stored in the database and a simple data query used to retrieve the correct data set. The application can also be given access to preexisting legacy database systems which can significantly increase the usefulness and economic value of the application. For example, an application could connect to an existing museum catalog or digital video repository.

The critical aspect of any scheme to provide database access to authoring tool is the variety of database system types that must be supported. The application author will choose the database system for a particular application based on the features of the system (e.g. price, platform availability, multimedia support) or on the necessity to interact with one or more legacy systems. This paper describes the design and implementation of a virtual database module that can be included in an application authoring tool. The software was embedded in the

AthenaMuse 2™ multimedia authoring system developed by the MIT Center for Educational Computing Initiatives [Harward 1994].

2 The Virtual Database Module

Every database system provides its own proprietary method for communicating with an application, known as the application programming interface (API). Obviously the application author does not want to learn a new API for every database system that needs to be connected to an application [Ram 1991]. The virtual database module [Figure 1] is designed to offer a *standard* method of interfacing a wide variety of database systems. Moreover, it may be necessary for the application to connect to multiple database systems simultaneously, and the virtual database module must allow for this [Hurson 1994]. For example, an application may allow the user to selectively download data from a remote database system managed by a publisher or library to a local database residing on his or her own computer. This is the type of functionality that is needed in software that allows a student to search commercial databases for relevant information and then store the results of those searches in an electronic notebook. It is also important that the programming interface to the virtual model reflect the needs of the application author. No prior information concerning the database, other than its system type and location, should be required to establish a connection. The structure of the database (the database schema) should be retrieved automatically upon connection by the virtual database system. The application's author can then use this information about the schema to construct appropriate interfaces for the software's user.

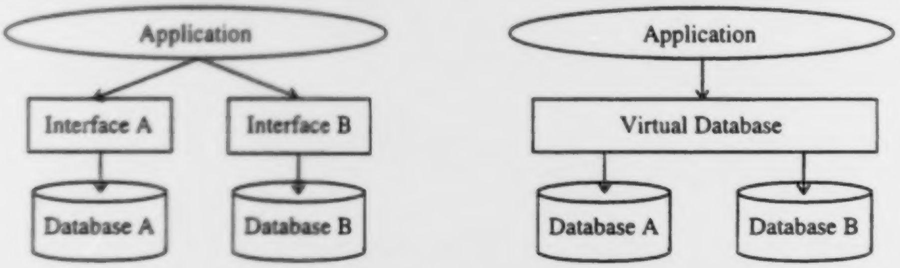

Figure 1: The virtual database provides a common interface to different database types so that the author can avoid using different APIs to connect to different databases

The Open Database Connectivity (ODBC) standard [Microsoft 1994] provides a standard API intended for use with relational database systems. The Object Database Modeling Group (ODMG)[Cattell 1995] has proposed a similar type standard for object databases. however, these standards to not address the problems faced by an application author who wishes to take advantage of both these types of database. In addition, the interfaces provided by these standards are not particularly easy to learn or use, nor do they provide all the functionality typically needed by an application author. Within the virtual database model, each standard is treated as a particular type of database system.

Since individual databases display different levels of functionality, the virtual database system must provide a flexible interface that allows access to the extended functionality of some databases while providing extra functionality to compensate for the more primitive database systems.

There were five steps in the design process of the virtual database module, each of which is summarized below. First, a standard database model was chosen for the virtual database. Second, standard data types were defined. Third, a standard query language was defined for data access. Fourth, a mapping process to transform component database systems to the virtual database model was designed and implemented. Fifth, an object-oriented user interface to the virtual database system was created.

2.1 The Virtual Data Model

The most important property of any database system is the data model upon which the system is built. The data model is a factor that critically affects every other aspect of the system. An important role for any virtual database system is to operate in an environment where multiple data models may coexist. The virtual database model must therefore be able to encompass a very wide range of pre-existing database system models [Hughes 1988].

The first widely used data models were the hierarchical and network models. Although superseded by the relational data model, these early data models are still found in legacy systems and file systems. The relational data model currently remains the most popular model for commercial database systems. The model is based on the concept of a relation: a set of ordered data tuples, such that each item in a tuple belongs to a specific data domain (e.g. integer, real, string, date)[1]. Compound data types such as lists, sequences or sets are not allowed as domain types in relational databases. This is perhaps the biggest disadvantage to the relational model. Closely tied to the relational model is the concept of data control and management languages which are provided with the model to allow the user to create, modify, delete and access data. Structured Query Language (SQL) is a widely accepted standard for a data retrieval and management language for relational database systems.

Object-oriented database systems are software systems that integrate technology from the fields of database systems and object-oriented programming languages [Bertino 1993]. The core concept of any object-oriented system is that each real world entity in the system is modeled as an object, and the resulting set of objects communicate with each other via messages. An object-oriented database system provides a means of making these objects persistent. Object-relational database systems have been developed to take advantage of the complex data types allowed in object modeling, while building on the strengths of the standardized query language and formal mathematical base of the relational model [Stonebraker 1996].

An object model was chosen for the virtual data model. It is the most advanced of the existing data models and is most capable of representing the complexities of multimedia data and hypermedia links [Booch 1994]. The flexibility of the object model enables it to capture the semantics of other data models without loss of information. One of the main features of object-orientation is the separation of interface from implementation. This allows the access protocol to the virtual database model to remain constant, while the implementation of the model varies according to the component database system involved. In this way, the incompatible internal details of component systems are kept hidden. The object model can take advantage of inheritance to define a class hierarchy that ensures the appropriate translation procedure is carried out for each of the different types of component systems. Classes can be specialized to carry out the translation process for relational database systems, and then further refined to carry out the translation for a particular relational database. The model is closely based on the object model proposed by the ODMG. In this way it is hoped that the virtual database module will itself conform to emerging object database standards.

2.2 The Virtual Data Types and Query Language

A key component of any database system is the set of fundamental data types from which class attribute and method definitions are built. An allowable data type in one of these definitions is either a fundamental data type or an existing class. The virtual database system defines a set of common data types and is then responsible for translating the fundamental types of the individual component database systems to and from the common types. The types defined for the virtual database module include simple types (e.g. integer, string), objects (e.g. date, sequence) and multimedia objects (e.g. image, sound).

The query language for the virtual database is derived from ongoing developments in SQL and the Object Query Language (OQL) standard prepared by the ODMG. Both the SQL3 [Mattos 1994] and OQL [Cattell 1994] standards are heavily based on SQL-92. These languages are both extended forms of SQL in that they implement a version of SQL that has been expanded to take advantage of the object data model. The two major extensions are to allow ***attribute path specifications*** and ***method specifications*** in queries. Attribute paths allow a query to refer to the components attributes of an object. For example, if an object of class Document contains objects of class Page, then a reference such as objDoc.page might refer to the first page of the document named objDoc. Methods are procedures which are components of objects and which can be executed on those objects. For example, a method named nextPage might fetch the next page of a document.

---

[1] Relations are often referred to as tables in the database, and tuples within a relation are often referred to as rows of the table.

The common query language for the virtual database is concerned with data retrieval only. Data and schema manipulation is possible, but is done directly through operations defined on the virtual database objects, not through the query language.

2.3 Transformation from Component Databases to the Virtual Database

The next step in implementing the virtual database module is to provide a methodology for translating each component data model to and from the common model. In keeping with the object model, the database user explores a database schema by examining the database class hierarchy and the properties of individual classes within this hierarchy. The translation process is responsible for creating a class hierarchy that adequately represents a component schema. Once the class hierarchy is established, the translation process is also responsible for providing access to the data stored within the database. This data is presented to the user as object instances belonging to a particular class. Where necessary, type conversion from fundamental component data types to common data types must be carried out. All these translation operations are transparent to the user who uses the same interface to access schema information and data objects for all component systems.

One of the problems in providing translation from real-world databases to the virtual data model is that some constructs that are supported in the virtual model are not available in some component systems. For example, some component systems do not support notions such as the definition of operations on data types or database keys. In addition, many real-world database systems do not support the full range of fundamental data types allowed for in the common virtual data model. In some cases, the virtual database is able to make up for these deficiencies by providing supplemental data translation capabilities between the virtual database system and the component database. In all cases, such deficiencies must be treated gracefully and should not interfere with the operation of the virtual database module.

The translation process for an object-oriented or object-relational database is relatively straightforward and requires the least translation effort. For a relational data model, every table in the relational schema can be translated as a class in the virtual object model. The class name is taken from the table name. Each field in the table is used to represent an attribute of an object [Albert 1993]. The hierarchical data model is composed of data elements arranged in a simple tree structure. A set of data element types is defined for the database, with each type consisting of a set of data fields. In the common object model, each element type is considered to be a class, and the data fields are interpreted as attributes. As in the relational model, the type associated with each field will be translated into a fundamental type belonging to the common model. Each data element becomes an object. Small changes in the process may be necessary for individual databases, or some databases may require the combination of techniques from different categories. The translation procedures are completely automatic, although database administrators may provide extra information to be used in the translation process by inserting this information in the component database itself.

2.4 The Virtual Database User Interface

The interface to the virtual database system that is presented to the application designer, and by extension to the application user, is extremely important in determining the contribution that the virtual database can make to improving the functionality of the application. It takes the form of a set of predefined database object classes. The designer can use these classes directly, or can derive more specialized classes for database manipulation through subclassing.

The interface can be divided into two main parts. The first part is a set of classes that represent the fundamental data types available in the virtual database system, while the second part is a set of classes that represent a connection to a component database and provide operations for schema manipulation and query construction and execution. An application author uses exactly the same interface classes to connect with any database supported by the system and the author may have several open database connections simultaneously. The common interface promotes data interchange between the connections and a multidatabase interface object is envisioned which would provide supplemental multidatabase operations [Bukhres 1996].

3 Applications

A sample of the applications developed to date are described here in order to provide an indication of the diverse database systems which have successfully been used to author and run applications with the virtual database module. Examples using relational and object-relational databases will be detailed. The purpose, complexity and target audience of the applications all vary widely.

3.1 The MIT Museum Edgerton Collection

The MIT Center for Educational Computing Initiatives and the MIT Museum recently completed a project to provide electronic access to the collected works of Harold Edgerton, famous as a pioneer of strobe photography[2]. The collection was cataloged using the object-relational database UNISQL/X™, which allows for the possible specification of hundreds of data fields. The ability of UNISQL/X to model complex data structures was of immense importance to the success of the project, which would have been very difficult, if not impossible, to complete using traditional relational database systems. The object-relational database also provides better facilities for storing image data, either in the database for small thumbnail images, or as references to external files for larger images.

In addition to using the database catalog for internal bookkeeping and reference purposes, the project created an interface to the database so that a museum patron can browse Edgerton's photographs. There are over 7,000 photographs in the collection, and it would be physically impossible to display all of the photographs together at one time. By providing a patron with the ability to query the database, the patron is able to search for photographs of a particular subject that interests him or her, as well as to browse the catalog at random.

The virtual database interface within the AthenaMuse2 authoring environment was used to implement this browser application.

3.2 New England Aquarium Kiosk

The virtual database interface was also used as part of an application developed by the MIT Center for Educational Computing Initiatives in collaboration with the New England Aquarium. This software operates as a kiosk in the aquarium in an exhibit about the flora and fauna of New England Ponds. The virtual database accesses stored information about the quality of local ponds, still images about various wildlife, and records about the video, audio and still images that are used throughout the application. Users can select ponds anywhere in the local area by clicking on a map of the region, and appropriate information relevant to the nearby pond is fetched from the database and displayed.

An important advantage of this software architecture is that the information on water quality can be updated without altering the application software. Any change in the underlying database is immediately reflected in the software the next time a query involving that information is made. New images, text and other media can be added simply by altering the database.

Many other applications have been written that take advantage of the virtual database module to provide a consistent interface for both media management and media access across a variety of object, object relational and relational databases and the file system. These applications include a generic database browser and a notebook type application that highlights the simultaneous use of multiple databases. The examples quoted in this paper show that the same virtual database interface can effectively utilize the very different characteristics of the underlying database in a manner which promoted the use of databases in the authoring and execution of multimedia applications.

---

[2] The Edgerton project was supported by the Edgerton Foundation and involved a large number of different individuals, including James Sheldon (Producer), Lynne Bolduc (CECI staff member), Kara Schneiderman (MIT Museum) and a number of other CECI and MIT Museum staff.

4 Extending the Virtual Database Functionality

The vast majority of applications that have been developed so far with the aid of the virtual database module., have simply used the virtual database to retrieve information that was initially stored in a database during the application authoring process. However, the virtual database also provides an excellent foundation for further research into the innovative uses for multidatabase technology within the application authoring environment. Two examples are application object storage and the dynamic evolution of applications.

A typical application can be divided into two parts, the application data and the application behavior. Until now, this paper has considered only the permanent storage of application data. A novel extension to the virtual database module has been implemented to allow the application behavior to be captured in a database, enabling the development of a new paradigm in application storage [Curtis 1996]. There are significant advantages to being able to both store and retrieve application objects from a database during the running of an application, including advances in error handling, collaborative authoring and the individual customization of application behavior depending on end user actions.

An application that is provided with a database connection can use that facility to update media data automatically [Dynes 1997]. Data updates might be stored in a centralized remote database to which the application connects occasionally. The updated data set is downloaded and inserted into the local application database. The application author can grant the application's users control over all or parts of the database so that they can modify the application.

5 Summary

The case is made for the use of databases in the development and use of multimedia applications. A virtual database module, present in the AthenaMuse2 authoring tool, is described. It provides a consistent programming interface for differing types of databases. Examples were detailed where this virtual database interface was used with object-relational and relational databases. The utility of databases in both the authoring and execution of multimedia applications has given rise to suggestions for innovative authoring styles. The virtual database module can be used to store application objects or to enable the dynamic evolution of applications.

Abstract: This paper is an overview of the design, development and implementation of an Internet-based application, *CyberRecess*^{TM}, designed for children from kindergarten to grade 12 (K-12) in which the setting of a particular context is used as the basis for the creation of dynamic, user-driven content. It attempts to integrate current learning theory and technology in its creation. The product is designed to maximize the contextual relevance to the learner through combining user-authored content with the communication abilities that the Internet makes possible. Using a learner-centred model and constructivist principles, we set out to create an application that empowers and challenges the student to engage in active learning. By virtue of a networked, interactive multimedia learning becomes location-independent and self-directed. Contextual relevance and dynamic content is automatically created through empowering students to author their own content.

Introduction

We are in the midst of a digital revolution that promises profound change in the way we work and learn. Enabled by technology, these changes result not only in new learning concepts, but ultimately in systemic and cultural changes in our educational institutions. The challenge for creators of learning multimedia applications has been to create applications that integrate learning theory with the effective use of technologies that are rapidly changing. The key to enhancing learning through the development of new applications is the creation of tools which are intuitive, relevant and that assist in the creation of environments that facilitate both the communicative and community aspects that are so essential to the learning process. Networked Interactive Multimedia (NIM) technologies such as the Internet and World Wide Web allow users to communicate with others on a global scale easily and effortlessly. Combining learning theory with these technological capabilities results in applications in which user-driven interactivity forms an essential part of this process.

Learning Theory

Learning is the acquisition of knowledge through study, experience, or instruction. Critical to this process is the use of high-level communication, demonstrated by shared ideas, critical thinking, debate and discussion. Current theories of learning and knowledge-building are evolving rapidly. Modern theories of constructivism suggest that knowledge is not merely a passive transfer between teacher and student, but is actively constructed by the learner. Recent research [Kafai & Resnik, 1996] investigating the use of technology in learning pioneered by Seymour Papert at the Massachusetts Institute of Technology suggests that when students are actively engaged in making some type of artifact that they can reflect upon and share with others, they are more likely to create new ideas. Central to this theory of "constructionism" is the notion that, in the learning process, the affective is as important as the cognitive - that is, forming new relationships with knowledge is as important as forming new representations of knowledge.

Another key element of constructionism is diversity. The recognition that learners have multiple learning styles and make associations and connections with knowledge in many different ways is revolutionizing our concepts of learning. Gardner's theory of multiple intelligences [Gardner, 1993] asserts that we each have separate human capacities. This is accelerating the focus on "individual-centered education". Finally, context is essential to the clarification and development of meaning. Communication of ideas and the sharing of knowledge with others in a community of learners also play key roles in the development of context.

Technology

Against this backdrop of learning theories, we have technologies that are revolutionizing our world but, to date, have had little or no influence in the classroom and in the ways our children learn. Traditional computed-based instruction (CBI) has tended to be "programmed heavy" and, while allowing for some interactivity, was designed essentially as an extension of extant pedagogical methodologies. That is, the user merely followed the course of study according to a programmed path and is not easily able to deviate from it. Most CD-ROM courseware follows this type of "structured interactivity".

The learning benefits of CD-ROM based, multimedia learning applications can be substantial and have been well documented over the years. However, there remain several inherent limitations to these applications:

1. These applications are designed using a paradigm that does not utilize the capabilities of the technology. Networked interactive multimedia (NIM) and, more specifically, the Internet allow for applications that are learner-centred and discovery-based.

2. Communication and collaborative learning with peers does not occur as part of the process. CBI tends to be isolationist with one student working on a standalone basis. The focus is on information and analysis without any communication. NIM, on the other hand, allows for communication between users and engenders collaborative work.

3. The subject matter is static and may not always be relevant. While considerable time and expense goes into the production of traditional software, the content is cannot be changed easily and is subject to rapid obsolescence. This is increasingly problematic in a world of rapid change.

4. Adapting the product to render contextual relevance is, at best, difficult. Context is an essential part of learning and, unless the application is dynamic and flexible, it will be limited in scope.

The 1990's, however, have brought about an entirely new generation of technologies that have transformed computers from machines that perform computations faster to essential tools for global communication. The Internet and the World Wide Web together with the new networked, multimedia-based technologies are reorganizing our world. Working with computers has changed from being a standalone, segregated experience to becoming a rich, ubiquitous, community-based experience.

The Concept

We set out to design an application that would have several characteristics that we had determined were important in addressing the shortfalls of CBI applications and, at the same time, maximize the functions of a NIM environment. The challenge was to create an application that would be contextually relevant, dynamic, maximize communications between peers on a nation-wide or global basis while, at the same time, effect substantive learning and be fun to use. Further, the use of the World Wide Web (WWW) and the Internet as an enabling medium was natural due to its low cost, ease of availability for most users and platform independence. The opportunity of engendering new social dynamics through the design of such an application did not escape us either.

After much deliberation, we decided to create Sympatico's *CyberRecess™* - an Internet-based application in which the contexts we provide would form the basis for the creation of dynamic, user-driven content. We were determined that we would create an application with a key difference! *The content is entirely generated by users for consumption by users.* Students effectively become publishers and, through communication with "contextual editors", they can shape the design and development of future contexts so that relevance of the application is assured from a user point of view.

CyberRecess™ is our first application in which a team of "contextual editors" merely set the context. The application has six basic sections that involve science, mathematics, English, art, humor and the "*Wired Goose Chase*"- a section that allows for the development of online research and navigational skills. Forums that allow for the creative expression of ideas will be added in the future. Any student with Internet access can participate in *CyberRecess™*. Submissions are screened and qualified by a team of editors and selected entries are posted. Because content is created by students, it is generally relevant to the user group. The experience is truly empowering as every child is presented with the possibility of authoring, publishing and sharing their work and experiences with other children elsewhere.

While this application is only a small first step in understanding learner-centred multimedia applications, it raises several future possibilities: Will a new social and cultural dynamic be created for students who have traditionally been isolated within the walls of the classroom and who can now communicate with other members of a larger learning community? Can students from other institutions and levels be used to manage the process and can this provide valuable "real-world" work experience for students? Will this foster mentoring relationships between students and experts? The possibilities are endless.

Design and Developmental Issues

There were several critical issues that had to be addressed as we progressed in the design and development of the application.

1. *Learning Goals* - were of primary importance in the design of the application. We have tried to develop an environment that encourages participation and discovery, and yet is fun and whimsical at times. There is a high level of interactivity inherent in *CyberRecess™* and the user has the ability to navigate anywhere they wish. This empowerment of the user is designed to foster attitudes of responsibility and social awareness while surfing online. User generation of content is key to maintaining a constructivist approach to application design. The idea that learning can and should be fun and motivating is paramount.

   A planned addition to development will look at the integration of curriculum-based concepts with the contexts that we set.

2. *Contextual Cascading* - a major issue we faced was the discrepancy in the cognitive domain and the comprehension abilities between eight year olds and twelve year olds. Social attitudes and the attempt to address these issues proved to be major challenges. We tackled these concerns by developing a system of "contextual cascading" in which each module progressively builds up to address higher levels of cognition. For example, the language section may start with a few items that play on words and which might be appropriate for an eight year old and, as the user drills down, the section gets more complex and may provide Internet links to bodies of literature that are more appropriate in addressing the attention span and learning requirements of a twelve year old. Users are always in control and they may choose not to proceed any further if the context is too complex for them. In this way, the abilities and skills of the user are emphasized rather than some arbitrary age-based standard.

3. *Community and Identity* - The most powerful component of the Internet is the ability to chat, participate in forums and generally communicate with others. The sense of community that this engenders is compelling.

In order to develop this sense of identity and community, we developed characters for each section. Within each character we have imbedded one or more of the multiple intelligences. This allows for a unique idiomatic expression that results from the interplay of character, form, intelligence and communication. Users can communicate with one another and with us through e-mail and we will eventually create forums to facilitate discussions between users.

4. *Navigation* - It is essential that navigation be intuitive. *CyberRecess™* has several sections that have to be easily adaptable for user contributions. Each change results in significant effort to reconfigure the navigational programming. During the design phase, several navigational formats were tested including the use of words only, the use of icons and a combination of the two. In addition, the ease of navigation was a primary consideration.

   When dealing with the issues surrounding navigation there is a fundamental tradeoff between "open navigation" - the ability to readily jump to any section of the application regardless of where one might be and "directed navigation" - having to always go back to the home page and then wend one's way to the next desired location. The former clutters the valuable real-estate of the screen with navigational icons while facilitating rapid movement to the desired location. The latter tests the threshold of user patience and can make navigation an onerous process. After much research and feedback from users, we adopted a hybrid-segmented approach that falls mid-way between the two paths described above. Users can always go to the home page, and to the lead page of a respective section that they are visiting, however every page will not necessarily provide access to any other page. This compromise position seems the most acceptable to users.

5. *Internal Development Processes* - An interesting aspect that arose from our developmental processes is the concept that we should be operating in the medium in which we design. After all we were adamant that we had to walk the talk to have any credibility. The necessity of being a high performance team within a "Learning Organization" was important to all the team members. With this in mind, we created a team that operated as a virtual team from their home offices and we created a collaborative development team with shared responsibilities.

   There are inherent problems with such a development approach. Generally, members struggle at first while attempting to establish the commitment and trust necessary for effective collaborative work. One must be ever watchful of the "design-by-committee" approach that can result in counter-productive behaviour. In order to address these issues, team members were given clearly defined responsibilities while at the same time they participated in "brainstorming" sessions that elicited the best from their experience. They continually surprised us through creating unimagined synergies and expanding and extending the application concept. The essence of this type of system is in striking the right balance between collaborative, "group-think" activities and production-based activities.

6. *Management of user-authored content* - is a significant concern. Typically, in multimedia development, a tremendous effort is exerted in the production of content and there is little effort expended in the on-going management of the content. With a user-driven authoring process such as ours, the tables are turned. Development is less "content-intensive" than traditional multimedia, but content management becomes a very significant issue.

   We sought the use of technology to obviate some of these processes and make the process more fluid. When we first started, submissions were primarily designed to be via E-mail and a programmer was required to code the submissions into hypertext markup language (html) and post them to a Web server. We tackled the issue on two fronts. First, we incorporated a Web-based authoring tool so that users could send their contributions directly to us coded in html. Second, we designed a series of templates and underlying databases to streamline the management of user submissions.

244

Implications

The implications of a user-authored, dynamic, contextual application such as *CyberRecess™* are significant:.

1. Preliminary information from surveys indicates that students will be motivated and learn faster as the inherent nature of the product demands interactivity. Passive learning is replaced with active discovery.

2. Interactivity and communication foster collaboration and a constructivist approach to creating knowledge. The online nature of the technology allows for a flexible, open-ended interactive experience and as content is user-created it is both current and relevant.

3. Teachers will have to adapt their teaching styles to suit the dynamics and capabilities of the new technologies.

4. Internet usage is being elevated from searching through a vast array of information to using the communication capabilities it provides to engender true inquiry, communication and higher order thinking skills.

Ultimately, we believe that these technologies will have a profound impact on learning cultures. Ideas and the ability to put them to productive use are the new currency of the Knowledge Age and we view *CyberRecess™* as being a small step on the journey in the creation of a culture of lifelong learners.

About the Authors

Manuel da Costa is the Development Manager, Learning Services at MediaLinx and is responsible for strategic and business development, research and application development as well as multimedia programming for the Learning Services Division. Manuel has extensive experience in business and education. He has previously taught high school science and was a business consultant with Ernst & Young for several years. He is a member of the Advisory Committee on Communication and Marketing Services for the Canadian Education Association.

Vikki Saunders is a Project Manager, Learning Services at MediaLinx. She has a degree in Music Education from McGill University, Montreal and in depth knowledge and experience in multimedia application development. Before joining MediaLinx she was a co-founder and President of Global Degrees, a company specializing in the development of educational multimedia products for the global marketplace.

MediaLinx Interactive, LP., is funded by several telephone companies in Canada and is in the forefront of developing, packaging and distributing interactive multimedia products and services. Its key service, the *Sympatico™* Internet Service, is Canada's largest nationally-branded Internet service and has received acclamation from around the world.

A Quantitative Approach to Navigation Paths and Behaviour of Inexperienced Users of Hypermedia Documents

Maria João da Silva Ferreira Gomes
Instituto de Educação e Psicologia
Universidade do Minho
PORTUGAL
E-mail: mjgomes@iep.uminho.pt

Abstract: This paper focuses on the problem of navigation in hypermedia documents. It describes a study which aim to answer the following questions: what do readers do when they are asked to find factual information from a hypermedia document with the goal of answering specific questions? What readers do when they are asked to study a topic, based on the reading of a hypermedia document? Is the navigation behaviour similar in these differents circumstances?

Two groups of students participated in the study. Group "A" was asked to answer to specific questions based on the content of a hypermedia document. Group "B" was asked to use the same hypermedia document but without having any factual task.

A program was written to generate a data file log that makes a trail of each of the individual navigation paths. An automatic treatment of the navigation paths was implemented to analyse the navigation behaviour.

Introduction

In 1987, Conklin in his well-known article "Hypertext: An Introduction and a Survey", said that "There are two classes of problems with hypertext: problems with the current implementations and problems that seem to be endemic to hypertext" [Conklin 1987, p.38]. Conklin considers that an "endemic" problem of hypertext is the "navigation problem" when he says that there is "(...) the problem of having to know (1) where you are in the network and (2) how to get to some other place that you know (or think) exists in the network." Since 1987, many of the "current implications" reported by Conklin have been resolved as the technology and the hypertext/hypermedia systems evolved but many aspects of the "navigation problem" remain. The "navigation problem" and the "disorientation problem" are reported by many authors [Campagnoni & Ehrlich 1989; Edwards & Hardman 1989; Kibby e Mayes 1989; Bernstein 1990; Boyle & Snell 1990; McAleese 1989, Jonassen 1990; Jonassen & Grabinger 1990; Nielsen 1990; Castelli, Colazzo, Mich & Moliaru 1991; Gay & Mazur 1991; Tricot 1993].

With our research study we have endeavoured to contribute to this major topic of discussion - "the navigation problem" - particularly in what educational uses of hypertext/hypermedia systems concern.

Our study was based on the idea that the answers to the navigation problems on hypermedia documents and the problem of "being lost in hyperspace" will only be known when we can understand and characterize the navigation patterns and behaviours of the users of hypermedia systems. To meet this objective it is important to use automatic register tools to keep track of the navigation paths' users adopts in different circumstances. This specific research tried to describe and interpret the navigation behaviour of users of hypermedia documents in different task context. To develop and analyse different criteria and "indices" to interpret the navigation behaviours was also a research aim.

Objectives

With this project we tried to characterize the navigation paths that inexperienced users of a hypermedia system adopt when they are assigned different tasks. We tried to determine if there are any differences -- and what kind of differences -- between a group of subjects who was asked to answer specific, factual questions based on the content of a hypermedia document and another group who was only asked to get information on the same topic and with the same hypermedia document but without any factual task.

Participants

The subjects who participated in the study were undergraduate students of University of Minho. They were studying Education Technology as part of their *curriculum* and a hypermedia document was used to give them an overview about hypertext and hypermedia technologies and their applications to education. The subjects participated in the study as part of their coursework. They were 25 female students and only 1 male student. This happened because that specific class includes only 3 male students (and 2 of them were absent). The students' average age was 24,5 years. All of the students had similar experience in the use of computers (e.g., word processing and drawing software) but none had previously used any hypertext/hypermedia document. They were acquainted with graphical interfaces (Windows or Macintosh) and input devices such as a "mouse".

The hypermedia document

For the present study a hypermedia document concerning the educational uses of hypermedia systems, entitled "Hypermedia: Myth or Reality?", was developed. The hypermedia document was created with the system "Toolbook" from Asymetrix Corporation. "OpenScript", the programming language of Toolbook[1] was used to create a program ("script") to register all the navigation paths of the users in a log file.

Procedures

One week prior to working on the hypermedia document "Hypermedia: Myth or Reality?", the students were introduced to the navigation process by attending a demonstration. For the demonstration a Toolbook document (a "book") with only six "pages" (information nodes) was used.

After the demonstration session the students were randomly assigned to group "A" or group "B". Students from group "A" were asked to navigate on the hypermedia document in order to answer factual, specific questions and to write the answers on paper. The students of group "B" were asked to navigate on the hypermedia document to get information in order to have a class discussion in the next class hour. Both groups of student were asked to work at their own pace, without time constrains.

---

[1] Toolbook uses the "book" as an interface metaphor so that each node of information corresponding to a screen is called a "page".

An automatic program kept an exact record of all of each student's navigation options.

Instruments and Measures

A key component of this study is the possibilities offered by the information of the logging data file created with "Openscript". The program to generate the data file was written in such a way that every "event" taking place when a student is in use of the hypermedia document was recorded. The data that was made available by the use of this "data log" program which we called "register tool" included:

- the name of each "page" (information node) visited,

- the time of entry in each page

- the objects clicked in each page ("hot-words", "links" and "pop-up windows" that were activate).

Fig. 1 shows the aspect of a piece of an individual navigation path, as recorded by "register tool".

Figure 1 - Part of a navigation path as traced by the register tool

It is important to note that each individual "data log file" consists of a large amount of information that would be impossible to analyse manually. A special program was written, using Pascal, to analyse the data file recorded by the "register tool". This Pascal program was named by us "Analyser" and it calculates the following values:

Amount of time using the hypermedia document------------------------ TT (Total Time)

Average Time the user spends in each "page" -------------------------- AT (Average Time)

Total Number of Visits to "pages" ------------------------------------- TNV (Total Number of Visits)

Number of Different "Pages" Visited------------------------------------ NDPV (Different Pages Visited)

Ratio $\frac{\text{Total Number of Visits}}{\text{Number of Document "Pages"}}$ ------------------------------------- TNV/NDP

Ratio $\frac{\text{Total Number of Visits}}{\text{Number of Different "Pages" Visited}}$ ------------------------------------- TNV/NDPV

Ratio $\frac{\text{Number of Different "Pages" Visited}}{\text{Number of Document "Pages"}}$ ------------------------ NDPV/NDP

Number of Supplementary Nodes Visited-------------------------------- NSNV

Total Amount of Navigation -- TAN=NSNV+TNV

The NSNV (Number of Supplementary Nodes Visited) represents the number of "hot-words", "hot-objects" or "pop-up windows" that were visited. This kind of "node" contains additional information, not very important for understanding the main concepts. The most important concepts were represented in the "nodes" which correspond to a "page". When we refer to "nodes" we are referring to one "page". When we refer to "supplementary" nodes we are referring to "hot-objects" embedded on a page.

The TAN (Total Amount of Navigation) was calculated as the sum of the NSNV and TNV and represents the total number of times the user interacts' with the document.

Tab. I describes the different indices used.

Index	Description	Notes
TT	Amount of time using the hyperdocument	------------------
AT	Average time the users spend in each "page"	------------------
TNV	Total number of visits to "pages"	It helps to understand how "deep" the navigation route was
NDPV	Number of different "pages" visited	It helps to understand how "deep" the navigation route was
TNV/NDPV	Ratio $\frac{\text{Total Number of Visits}}{\text{N. of Document Pages}}$	It helps to understand how "repetitive" the navigation route was
TNV/NDPV	Ratio $\frac{\text{Total Number of Visits}}{\text{N. of Differents Pages Visited}}$	It helps to understand how "repetitive" was the navigation route
NDPV/NDP	Ratio $\frac{\text{N. of Differents Pages Visited}}{\text{N. of Document Pages}}$	It helps to understand how "deep" the navigation route was
NSNV	Number of Supplementary Nodes Visited	It helps to understand how "deep" the navigation route was
TAN	Total Amount of Navigation	It helps to understand how "deep" the navigation route was

Table I - Description of the different indices used

Data Analysis - Results

The program "Analyser" calculates all the indices described in table I based on the data log file of each subject created by the "register tool". After that, we calculated the average and standard deviation for each group of subjects and each one of the indices. Nonparametrics statistics with the Mann-Whitney ("U" test) were also calculated in order to analyse the significance of the differences between the two groups.

Tab. II presents the average and standard deviation for each index and each group of students. It also presents the results the "U" test of Mann-Whitney.

BEST COPY AVAILABLE

	Group "A"		Group "B"		
	Average	Std.Dev.	Average	Std.Dev	Mann-Whitney Test
TT (minutes)	43,0	12,3	39,2	(15,7)	**n.s.**
AT (seconds)	23,0	7,6	15,7	(11,3)	**$p<0,05$**
TNV	115,8	44,8	175,0	(75,9)	**$p<0,05$**
NDPV	27,1	3,8	29,8	(3,2)	**n.s.**
TNV/NDP	3,6	1,4	5,5	(2,4)	**$p<0,05$**
TNVN/NDNV	4,2	1,4	5,8	(2,3)	**n.s.**

NSNV	25,5	12,8	34,5	(15,4)	**n.s.**
TAN	129,8	47,1	191,8	(65,6)	**$p<0,01$**

Table II - Average and Standard Deviation for each group and Mann-Whitney test of statistical significance.

From the data recorded on tab. II, it can be observed that, for most of the indices used, the standard deviation related to group B is higher than that of group A. This is not true for the NDPV (number of different pages visited) which we think can be caused by the small size of the hypermedia document (only 32 pages) and by the fact that, as all the subjects could navigate for the time they wanted, they had enough time to see all the existing pages. In this case it could be important to analyse the navigation paths in differents units of time, trying to assess if the initial behaviour of the user was different in the two groups.

We think that the tendency for smaller standard deviation found in group A indicates that the existence of a specific, factual task of information retrieval can reduce the individual differences between subjects in what concerns their navigation behaviour.

The average value of the TT (Total Time) of using the hypermedia document is higher in group A than in group B, but without statistical significance (n.s. - difference not significant).

The AT (Average Time) of node consulting is different for the two groups ($p<0,05$) being higher for group A. *This can indicate that individuals from the group to which a specific task was assigned (group A) spend more time reading the content of each node.*

Individuals from group B seem to have tried a path that includes many nodes without spending as much time reading the content. This idea is supported by the fact that group B presents a smaller AT of node consulting but higher values in what concerns the indices TNV (total number of visits); TAN (total amount of navigation) and ratio TNV/NDP. The differences found between the values of indice TM, TAN and TNV/NDP are also statistically significant.

Group B presents higher values than group A in all the indices related to the NDPV (number of different pages visited)but these differences do not have statistical significance.

Discussion and Conclusions

The results from this study suggest that the nature of the proposed task influence the behaviour of users of a hypermedia document. The results show significant differences between the group of students to which a specific task of retrieval information to answer objective questions was assigned (group A) and the students to which a less concrete task of "getting information about hypertext/hypermedia" was assigned (group B). Note that all the students of group A wrote the correct answers.

From this study it was found that:

- Individuals from group "A" seem to read the information contained in the hypertext document more carefully. They stayed more time in each node ("page") of the hypermedia document (group A: 23,825 second *per* node *versus* 15,698 second *per* node - group B ($p<0,01$)) and they answered to all the questions asked successfully.

- Individuals from group "A" also seem to have more similar navigation paths than those of individuals from group "B" (individuals from group B have higher standard deviation for all the indices than individual from group A). This evidence suggests that the task of "getting information to answer factual questions" results in a kind of "homogeneity" of the navigation behaviour (considering the criteria adopted).
- Individuals from group "B" visited more nodes ("pages") of information than individuals from group "A" but they stayed less time on each hypertext node, which suggests they were trying to have a more general view of the content of the hypertext document. They also visited the same node several times but in many times they stayed just a very few seconds on the node (almost the necessary time to make active another link) which suggests they were trying to make sure they had already "taken a look" at the information contained in the hypertext document (some of the individuals reported this intention).

These evidences of the influence of the "task" on the navigation behaviour are consistent with the results of [Fowler & Murrey 1987; citated by Stanton & Stammers 1990] and [Trumbull, Gay & Mazur 1990], whose studies despite using differents approachs, points in the same direction.

Abstract

Developing hypermedia instructional environments is a labour intensive enterprise, and there are certain inefficiencies inherent in current design, development and production methodologies and in the tools which drive these methodologies. Arguably, certain improvements in overall development and production time can be achieved with new tools. In particular, tools which can support iterative design and testing and the various phases of development and production, all within one integrated environment, might provide the basis for compressing the cycle of design, development and production. In this paper we argue that such tools can be developed by marrying database technology with the capabilities of media presentation software. Two examples of this approach are discussed. The first is a course development environment. The second is a tool that supports the design, development, production and maintenance of interactive scenarios.

Introduction

Developing computer-based learning, particularly hypermedia environments, is a time-consuming enterprise. In fact, instructional development is one of the few areas in which the intrusion of computer technology has actually increased rather than decreased product development times. The reasons are largely related to the nature of current methodologies and tools.

There are really two general methodologies that can be followed. Each has its own pitfalls and advantages but both are relatively inefficient. In this paper, we first describe, very briefly, the two methodologies, and pinpoint the reasons for their inefficiency. We then suggest that part of the problem is that existing tools support, and limit us to, these particular methodologies. We argue that a different, more efficient, model for development and production can be implemented with tools designed with a somewhat different philosophy in mind. What must be built is a single environment which a) supports iterative design and formative evaluation, b) integrates development and production phases, and c) offers the efficiencies of templates but provides greater flexibility than existing authoring environments and shells. The technology required is available presently based on the creative marriage of database capabilities with media presentation software. Finally, we describe two authoring tools under development which we have designed with this approach.

Methodologies for Instructional Development of Hypermedia

Currently, instructional multimedia development follows one of two models. In the first, a traditional, procedural instructional systems design (ISD) methodology drives the process. The second is based on rapid prototyping.

ISD Driven Approaches

In the first approach, there are discrete steps which follow in a more or less linear sequence: identify content, develop objectives, select instructional or presentation strategies, select media, develop standards and style guides, develop content (script, storyboards), produce media components. Following these various design and development activities, there is the production phase in which all the content is integrated within some functional application.

There are two variations within this approach, which depend on choice of technology. One option is to utilize an authoring shell, a kind of preprogrammed template or model into which the content is poured. The shell may be custom built: a one-off design programmed for a particular application. Or, it may be a commercial shell. In either case, there are problems with the overall methodology.

Using a commercial shell is not acceptable to most developers. Shells typically have their roots in earlier CBT models. They tend to have limited support for multimedia, and their designs are too constrained, too inflexible. Moreover, existing products do not succeed in furnishing a seamless environment for manipulating and integrating media components. An alternative to using a pre-designed commercial shell is to produce a custom-designed shell using either a media presentation tool, a hypertext authoring tool that supports multimedia, or a CBT authoring environment that supports multimedia. The problems here are as follows:

- the process is time-consuming and justifiable only in the context of larger projects or, at least, larger budgets,
- such shells are generally one-offs which are not re-usable or readily adapted to other projects,
- the process of designing the shell must take place at least concurrently with the overall content design and development process and this concurrency, which involves teams of individuals with separate kinds of skill and knowledge, is difficult to manage and coordinate successfully and cost-effectively,
- development of specifications for the shell usually proceeds through a prototype development process which is costly and inefficient: the tools employed for rapid prototyping and representation of designs and capabilities are rarely the same tools which will be used to construct the actual shell
- even when a custom shell is engineered, it will not typically provide a seamless environment for manipulating and integrating the different media components and therefore considerable technical expertise will be required to assemble the final product,
- development occurs in a separate environment which does not allow for testing the usefulness of linkages among the elements of content, or for otherwise effectively managing the design of a document with many cross-links.

These factors contribute, collectively, to the substantial overall development times and costs associated with hypermedia projects.

Rapid Prototyping

An alternative methodology utilizes rapid prototyping to design the product through an iterative process. This approach has the advantage that it builds in formative evaluation from the outset, as an integral part of the development process. Thus, the likelihood of costly revisions to the design being required at the production stage are minimized, as compared with a traditional ISD or traditional software development approaches.

However, all the problems mentioned above with respect to the enterprise of building a custom shell apply once more:

- the inefficiencies attributable to one-off results and the use of different tools for prototyping and for final production,
- a design and development process which is difficult to manage,
- and the separation of content design and content development environments.

A Technical Solution

What is required, if product development and production is to be made more efficient, are development tools which offer the following capabilities:

1. They should accommodate different templates for different projects with their own specific requirements regarding structure, navigation, user options, interface design.
2. They should furnish a production environment which allows a person without technical training to manipulate, organize, structure and integrate different media and generate the final product.
3. They should also represent a development environment in which content can be composed and formatively tested in a hypermedia format.
4. The content (the media assets) should be maintained in a form that makes it easy to access and review content either for use in a specific project or for re-use across new projects.

Our argument is that product development times can be improved if these criteria are met. The main thrust of the approach is thus:

- to allow development and production to take place in a continuous process within one environment,
- to place tools in the hands of the content developers which will allow them to produce the final product with minimal effort, and,
- to provide tools which will allow for the testing of organization and functionality from the outset of the content development phase (something which is problematic when content development is carried out with word-processing or desktop publishing software).

We are currently building two tools which meet these requirements. The first is an environment for building hypermedia documents. The second is a tool for building interactive, branching scenarios. These tools are described below.

The Hypermedia Builder

Designing and developing interactive multimedia courseware requires several steps typical of most development of instructional material. The major steps are: identifying learning objectives, developing content, structuring and linking content, producing the necessary media assets, and developing and producing the "shell" through which the content will be presented to the learner.

Shell development requires the involvement of a multimedia developer, who programs the software and integrates the media assets. This creates a dependency on the developer since very specialized activities requiring technical knowledge and skill are involved. It is expensive and typically not conducted on site. It creates a lag between the design of the shell, the development of the content and actually seeing results, which only then can really be evaluated.

The Concept

The idea behind the Hypermedia Builder is to provide an environment in which the content developer can not only create and structure content and questionnaires, but build and test hypermedia/hypertext links, integrating media components, indexes, glossaries, references and feedback.

An important feature of this tool is that as soon as content begins to take form, the content developer can start to view it from the learner's perspective. Once the content and structure is completed, the content developer can generate, through a straightforward process, the package that will be given to the learner. In the case of more elaborate and bigger projects, this package can also serve as a fully functional prototype on which a more elaborate production could be based.

The Application

The process of creating a new course begins by creating a new database in which all information for that course will be stored. There is no preset procedure. All relevant information can be added in the order most suitable to the author. One can start developing bits of content at a time, or go systematically one module to the next.

For example, one may start by first integrating media assets into the database with the Media module. The media assets can be graphics, sound, animation, digital video, QuickTime VR, as well as other interactive components such as tests, tasks or games. Each are stored with specifications inherent to their identity, such as width, height, duration, sample size, and so forth. Different aspects of the content are then developed within the following modules:

- the Main screen in which courses are created and opened,
- the Modules screen in which modules are added to the course,
- the Sections screen in which text, indexes, glossaries, references and media elements are added to the module,
- the Questionnaires screen in which questionnaires are added to the course,
- the Questions screen in which questions and feedback are added to the questionnaires.

As the content of the course is developed, the content developer can use built-in features to integrate all the information together. Important features are as follows:

- any media can be assigned to any individual section,
- hypermedia links can be assigned to specific bodies of text,
- voice overs and embedded tasks can be assigned to any section of a module,
- personalized indexes and glossaries can be built,
- questionnaires can be built and linked to any module,
- questions can be supported by any media, and linked to any section,
- answers to the questions can incorporate individual feedback,
- references can be inserted anywhere in the text.

As materials are integrated and the structure is elaborated, the results can be viewed directly within a variety of generic and/or custom learner interfaces. This allows the content developer to view the final product immediately, thus verifying the effectiveness of her intentions without delay.

The Hypermedia Builder provides a single integrated environment within which content developers may write content, develop course structure, conduct formative evaluation, and achieve final production. Since the tool is structured around and driven by a database engine, the task of course revision or modification is simplified. The prospect of being able to manage a large repository of media assets in order to produce course modules in a cost-effective manner is greatly enhanced.

The Hypermedia Builder offers a set of interface designs or templates for the learner interface, from which the developer may select. If need arises, these standard designs can be modified to meet specific requirements of any project. Over time, a large selection of interfaces could be developed to satisfy the needs of most learners.

The Scenario Builder Tool

In the contexts both of training and education, there is increasing demand for greater interactivity to be built into materials. In particular, of late, there is a great deal of interest in the use of interactive scenarios [Cognition and Technology Group at Vanderbilt, 1992; Shank, 1994]. Extended scenarios are seen as a vehicle for developing problem-solving skills, while scenarios in general are regarded as effective tools for transferring skills and knowledge to operational environments, for developing soft skills [Kass et al, 1994], for teaching processes and procedures, for teaching via story-telling [Feifer & Hinrichs, 1992] and for increasing the learner's interest and motivation.

Unfortunately, scenarios, particularly those with complex branching structures and dependencies, are difficult to design and, owing to the logic, time-consuming to produce. Again, we have applied the rationale outlined above, this time to produce a prototype, Scenario Builder, which facilitates the design, formative evaluation and production of interactive scenarios. The tool also simplifies the maintenance or modification of scenarios, and the re-purposing of existing scenario material or structures for new projects. As with the Hypermedia Builder, the idea has been to combine a custom multimedia-capable database with media presentation software. The result is an environment in which scenarios can be built up in a frame-by-frame iterative design process. The tool keeps track of the emerging structure, which can then be tested and modified on the fly. The number of options and/or number of decision points can be modified easily and the entire structure of branching paths is automatically adjusted accordingly.

The environment can be used for development and formative testing and also for final production. Each frame can contain text, graphics, sound, animation or digital video clips. These media assets are contained in a database, readily accessed, reviewed and placed in the scenario by the content developer without the need for technical expertise.

Different media components are accessed and structured directly within the environment of Scenario Builder. Currently, it is being developed to include the capability to take snapshots right in a work environment, using a video recorder, so that operational environments and scenarios can be easily and accurately modeled and depicted. The environment will allow for the direct capture and integration of voice or video, either for development purposes or for final production. Thus, Scenario-Builder is also a powerful tool for capturing and modeling specific processes or procedures, whether they are heavily branched or essentially linear. Finally, any material constructed with the Scenario Builder will be treated as a media asset within the Hypermedia Builder environment.

Scenario Builder thus represents an integrated environment to design, prototype, evaluate, develop, produce and maintain interactive multimedia scenarios. The integration of these tasks within a single environment, which can be used by an instructional developer who may lack programming skills, should provide significant efficiencies.

Conclusion

We have described two tools which are intended to provide an environment in which content developers can carry out design, development and final production work in a continuous process. By integrating these tasks, and by automating certain production tasks (such as building links and navigation tools), certain efficiencies should result. First, there is less requirement for technical programming skills. Secondly, materials do not have to be translated from the development environments (word processing packages, separate databases and so forth) and implemented in a separate production environment.

Of course, many of these objectives have been achieved with other products, including a host of commercial applications. The more unique contribution of tools such as Hypermedia Builder and Scenario Builder lies in their integration of development and production environments within a database driven system.

An added dimension to Scenario Builder, not discussed above, is that it could serve as an environment for learners to build and explore their own scenarios, or to model processes or procedures. These activities could be carried out individually or collaboratively. More generally, Scenario Builder could also serve as a useful tool to support scenario-based design activities for system development [Carroll, 1995].

Abstract: Increasingly, educators and professionals whose expertise lies in the area of computer technology are working collaboratively, with the goal of providing enriched technology- based learning experiences for students. Yet, little consideration has been given to how the culture of such technical communities interacts with that of the schools, potentially influencing the effectiveness of such school change efforts. This paper explores this issue, drawing on interviews, field notes, and archival data collected over four years as part of a case study of the introduction of the Internet into a large urban school district. The findings shed light on the need to make explicit cultural values and norms and to work to develop effective ways of bridging cultural differences between educators and computer professionals in order to facilitate productive collaborative efforts to implement technology- supported learning.

> Educator: You know, I think what happens is the education people look at it one way, the tech people look at it the other way. There's tension there which I think originally was a very creative, productive tension. But to me it's deteriorated to the point where I think it's debilitating to the project rather than adding a creative force...

Increasingly, school personnel and technology experts are working in collaboration, seeking to improve technology-based learning experiences for students [Lyman 1996]. Collaboration appears both sensible and necessary. Yet, as the educator who speaks above laments, it is one thing to aspire to a collaboration and another to realize its potential.

This paper describes issues that have arisen in Common Knowledge: Pittsburgh (CK:P), a collaborative effort designed to bring Internet access to the Pittsburgh Public Schools. As a collaboration, CK:P is designed to draw on the unique insights and expertise of public school, technical, and university personnel. A project education staff, comprised of former classroom teachers with non-technical backgrounds, is responsible for training teachers and supporting curriculum development. They also typically communicate teachers' needs to the project technical staff. Technical personnel, based at the Pittsburgh Supercomputing Center, include individuals with diverse skills relevant to implementing school-based networks. Their previous experience with educators is limited.

As others have noted [Crowson & Boyd 1993; Knapp 1995], there is a need to consider forces and conditions that impinge on collaborative efforts; however, there has been little analysis of organizational issues that may affect such ventures. Here, we describe key features of technical and educational workplace cultures and explore how cultural factors have affected CK:P's efforts to implement networking technology. Our purpose is to illustrate how contrasts in the norms, values, and routines associated with professional cultures can affect collaborative efforts. It is important to note that despite the tension and conflict described CK:P has accomplished much in four years - getting 64 schools on line, cultivating many Internet-based classroom projects, encouraging demand for technology from teachers, and developing a distributed system architecture. Yet even more might have been accomplished if the collaboration had worked more smoothly.

Methods

We draw on qualitative data collected over four years time, including email, field notes taken at staff meetings, and interviews with the technical staff, educational staff, and public school teachers responsible for using networking technology. Field notes and interviews were audiotaped and then transcribed. Each of the data sources was coded and analyzed using established methods such as those described in [Miles and Huberman 1994] and [Corbin and Strauss 1990].

The Professional Cultures In Question: Key Characteristics

Below, we identify and compare cultural aspects of the educational and technical worlds as they were evidenced in CK:P. In doing so, we do not assert that all members of the educational and technical staffs perfectly reflect these descriptions. Rather, these are factors that individuals embedded in their cultural settings are both aware of and orient towards, though they might individually reject or resist them.

Contrasting Values: Innovation vs. Tried and True

CK:P's technical staff value experimentation and development; they are interested in playing with and deploying new, cutting edge systems and software and are motivated by the challenge of improving existing systems. Thus experimentation may take place purely for its own sake; that is, even when practical implications are not immediately apparent. The emphasis on experimentation and development means also that CK:P's technical staff operate in a culture where change is the norm. Individuals routinely adjust to new situations, update skills and acquire new ones; indeed they must do so to survive professionally.

In contrast, CK:P educators are part of a pragmatic professional culture where members prize tried and reliable practices with predictable outcomes. Teachers - ever short on time - seek things which work. They are most interested in things with immediate application that address practical problems. Further, though many CK:P educators are open to exploring new technology, many are not comfortable frequently changing established classroom routines in response to technical updates since they feel this will likely be disruptive.

Contrasting Rhythms and Routines: Flexibility vs. Structure

Both PPS teachers and PSC technical personnel emphasize that rhythms and routines in their institutions differ from other workplaces, but the images they convey are strikingly different. CK:P's technical staff describe a relatively unstructured work setting tolerant of divergent work patterns and individual preferences. While priorities and deadlines are set, individuals determine work hours and how they will approach particular tasks. Often they work at home, at night and on weekends, rather than during conventional work hours.

Teachers' lives, in contrast, are dictated by a set daily schedule and structured work setting. They have little choice about who they will see, or when they will complete certain tasks. Further, unlike technical colleagues, teachers have little choice about where they will work. Thus, teachers are ever aware of timing, as they must complete tasks in a particular room in a pre-specified amount of time.

Contrasting Norms: Autonomy vs. Social Control

CK:P's technical staff included individuals who could be considered "hackers" or at least as having been quite influenced by hacker culture--which tends to be individualistic and idiosyncratic and to embody an ethic of toleration for what others might consider strange as well as disdain for those who impose rules and regulations [Sproull, Kiesler, & Zubrow 1984; Turkle 1984].

In contrast to this emphasis on autonomy and self-direction in the technical world, scholars have pointed out the inherent conservatism of the teaching profession [Lortie 1975; Metz 1990; Sarason 1972]. Teachers, who work incessantly with large groups of students tend to control what, when, and how material is presented; to direct student movement and interactions; and to dominate classroom discourse [Goodlad 1984]. Educators involved with CK:P differ from this in the sense that many favor pedagogical and curricular reforms that could prove disruptive to existing classroom relationships and authority structures. Yet, as adults in a world of children, and as the person ultimately responsible for students' safety, deportment, and learning they often felt the need to exert their authority and to emphasize the importance of order and social control.

Contrasting Orientations: Mastering an Instrument vs. Using a Tool

For CK:P's technical staff, computers are instruments which demand care, warrant tuning, and require continued practice to master. Willingness to "play" with technology is seen as critical as technical staff believe that it is only by making mistakes that one builds technical expertise. Consistent with this, they hope teachers will not only broaden their knowledge of Internet resources but also their knowledge of hardware and software. As one put it, "I do not believe in making systems easy enough for an idiot to use....if you make it that easy, people will learn nothing and you will be stuck supporting them for the rest of their lives."

In contrast, for CK:P educators computers are a means to an end - tools to enhance the curriculum or student interest in the curriculum. The education staff thus seeks to familiarize CK:P teachers with network resources, and encourages teachers to spend time on line becoming comfortable and familiar with the Internet. Beyond this, they are concerned that user administrators gain enough technical knowledge to maintain school-based machinery. However, rather than advocating the development of high levels of technical expertise, they have argued that user administrator's tasks should be easy, quick, and guided by documentation.

Interfacing Between Two Worlds: Implications for Implementation

The cultural differences just discussed are reflected in unvoiced assumptions, competing agendas and conflicting technical expectations. Such assumptions, agendas and expectations have slowed project implementation, wasted employee effort, and affected employee morale. To illustrate this, here we briefly describe instances of culturally based conflicts.

Cultures Create Assumptions: The Case of Printing

The CK:P technical staff have had to prioritize the tasks associated with implementing school-based access to the Internet. Typically, they worked first to deploy machinery relevant to Internet access. Printing capabilities were deemed a low priority and were significantly delayed. As a result, teachers felt that their needs were not met and did not use the Internet as much as they would have had printing been available. In hindsight, it is apparent that the educational staff assumed that the technical staff understood the importance of printing, while the technical staff assumed that printing was relatively unimportant.

The technical staff's failure to anticipate printing's importance to teachers can be understood largely in terms of two cultural factors: their immersion in a world characterized by flexible workplace routines and their preference for experimentation and cutting-edge technology. With the technical staff generally able to log on when and where they please and the expectation that interactions between coworkers can occur at off hours, paper-based communication is viewed as redundant and not necessary to insure that all have the same information. Assumptions about printing's lack of importance were likely exacerbated by the technical staff's preference for experimentation. As one put it, "[People in the technical world might say] 'Oh, it's just printing. It doesn't involve TCP/IP and networking and...' blah, blah, blah, blah. It's not as sexy, and so I think we gave it a lower priority because of that." In contrast, for educators in a structured world paper remains essential for communicating efficiently and regularly with student co-workers. Neither teachers nor their students have guaranteed home access and paper frees class time. Teachers do not have to wait for students to copy assignments from the board or organize time so that all have the opportunity to look at a computer screen.

Cultures Create Agendas: The Case of "Oberon"

Contrasting technical and educational cultural values have also been reflected in competing project agendas. Consistent with a preference for experimentation and comfort with change, for example, the technical staff has put in place a networking system that will allow continued development. Particularly during the first two years of the project, they also championed frequent system improvements that would enhance efficient administration of the network. In contrast, reflecting a pragmatic outlook, educators tend to ask first and foremost for a reliable and predictable system. While they do favor system improvements that enhance their ability to carry out curriculum projects, at times they frown on improvements with limited educational relevance.

To illustrate the implications of this dynamic, we describe an incident involving the system server ("Oberon") which provided teachers' access to the Internet during the first two years of the project. During the project's second year, CK:P's system administrator learned about a newly available update for Oberon's operating system. Excited that the update would streamline some system administration tasks, the administrator deployed it during the 1994-1995 PPS holiday break. Returning from vacation, educators discovered to their dismay and in some cases outrage that this technical experimentation had several ramifications for educational practice. Most notably, some teachers lost the ability to create student accounts. In addition, teachers lost access to Internet Relay Chat. Over four weeks, the education and technical staffs received telephone calls and 22 written email messages concerning lost access to curricular resources. The incident precipitated substantial project conflict, leading to hours of discussion but no completely acceptable solution.

Cultures Create Expectations: A Case of Software Development

Contrasting visions of computers and the knowledge that technology users should possess are reflected in expectations for the project's technical products, including software and documentation. Here, we describe discussions about a software package called PC-Remote Build. This package is designed to help PPS teachers who function as user administrators prepare computers for network access and also to "restore" CK:P supported software packages to a machine without destroying or removing local, non-CK:P supported software that teachers have added on their own volition. However, PC Remote Build has the disadvantage of removing program icons that indicate the presence of teacher-installed local software on a machine. Realizing this, and consistent with their orientation towards mastering technology, some technical staff members initially argued that teachers should seek the knowledge needed to overcome this product limitation: "The ed staff wants something no one has to touch....we want something that will do the job. And if that means that you have to have some understanding about how Windows stores files, then it means you have to have some understanding about how Windows stores files." From the perspective of the education staff and project director, however, such arguments are not valid. They do not view PC Remote Build as viable because it requires too much technical expertise - it is not a user-friendly tool.

The technical staff has responded to this criticism by declaring some of the package features "dead," agreeing to redesign the user interface, and reiterating the software's merits. From their perspective, the educational staff's fixation on a restore function that ignores local software blinds them to the benefits of the package: "...somebody with a technical background realized how advantageous this package would be because nothing like it exists, whereas the ed staff completely misses the point of the project." However, the education staff, believing the ability to restore machines without touching local software critical, remain unsatisfied.

Towards Improved Collaboration

With interest in the educational uses of networking technology growing steadily, it is likely that interactions and collaborations between educational and technical professionals will become increasingly common. It appears to us that at least three approaches might be taken to facilitate more effective collaboration. First, collaborations might consider creating roles for personnel with both mediation skills and knowledge of the norms, values and routines of collaborating institutions. Such individuals might serve as translators of sorts, facilitating interactions and ideally anticipating misunderstandings that might arise. Second, collaborators might investigate and make explicit professional cultural values and norms, and then specify before the fact matters related to information sharing, pooled resources, roles, and conflict-resolution procedures. Finally, collaborators might work in the same physical space to help them become more familiar with the work conditions and constraints each face. A modified version of this sort of arrangement has been tried recently with marked success on the CK:P project.

Not all potential pitfalls in technical-educational collaborations can be foreseen, but if schools intend to embark on such they might anticipate the possibilities of such problems and build in processes for recognizing and resolving them.

TATE: ISDN-based Videoconferencing in Preservice Teacher Preparation

Sean DeMonner, Director of Technology Services
School of Education, University of Michigan
demonner@umich.edu

Abstract: TATE (Technology Assisted Teacher Education) is a preservice teacher preparation project underway at the University of Michigan. The project utilizes synchronous videoconferencing to facilitate classroom observation and the discussion of teaching practice between current and preservice teachers. This paper focuses on educational issues of the project as well as the technical setup, budget, support considerations and outcomes. The full text of this document may be found online at: http://demonsterweb.oit.itd.umich.edu/tate/tatefull.htm

Introduction and Background

In the summer of 1996, Dr. Anne Ruggles Gere of the University of Michigan School of Education embarked on a project to use videoconferencing tools to provide preservice teachers with a more thorough knowledge of practice than has been available in the past. The resulting project, TATE, is the first in a series of distance learning applications in the area of preservice teacher preparation at the School. Lessons learned from the pilot will be used by Dr. Gere and other School faculty in making authentic external observation environments available to their students. This paper briefly summarizes the educational setting, instructional and institutional objectives, technical considerations, budget issues, instructional methodology, and outcomes of the pilot project.

But first a few words on nomenclature: Over the past several years the phrase *distance learning* and its variants have become loaded with implicature for most readers, and it is with some reluctance that we use this terminology in reference to our project. This reticence is largely the result of the dissonance between what is typically conceived of as distance learning (i.e. an instructor lecturing to remote sites via videoconferencing tools) and our implementation. In short, TATE is much more oriented toward close observation of classroom and inter-student dynamics, and collegial discussions between preservice and exemplar active teachers than *talking head* information delivery. However, lacking a more universal term to describe this application of synchronous videoconferencing and observation, and in light of the need for a common vocabulary, we will refer to the set of technologies in this project collectively as distance learning.

Another important piece of background information to understand is that this project is taking place in the context of a partnership between the U-M School of Education and the U-M Office of Instructional Technology. This partnership provides an extremely rich environment in terms of technical support, expertise and resources.

Educational Setting

TATE is a technological extension of a semester long co-mentoring program between U-M undergraduates and grade school students in Southfield, MI. The student pairs work together providing the undergraduates with direct experience with pupils, and the 6th graders with personalized instructional feedback and attention. The undergraduates also have the opportunity to observe Ms. Schiller (one of the first teachers certified by the National Board for Professional Teaching Standards) in action, as well as discuss with her various aspects of practice.

The University students travel to the classroom to make first-hand observations and to have direct contact with their partners. This level of direct observation and interaction is impractical for more than a few sessions however, particularly when the distance between the schools and the impact of 25 additional adults in the grade school is considered.

Neither set of students are technologically advanced in terms of computing skills, but like most students in the 90's, they do have very high standards regarding audio and video quality.

Instructional and Institutional Objectives

The instructional goals of the project were determined by Sean DeMonner and Ron Miller in consultation with Dr. Gere and Ms. Schiller. The institutional goals were defined by key faculty, administrative staff, and technical support personnel on the SOE/ITD Partnership committee.

There are three primary instructional objectives of the project:

- Allow preservice teachers the opportunity to observe Ms. Schiller's class without undue impact
- Provide preservice teachers with the opportunity to discuss practice with an exemplar teacher
- Provide Dr. Gere and her students with a common observational frame of reference upon which to base their discussions of teaching methodologies

The institutional goals of the project include:

- Understand the capabilities of emerging distance learning technologies and gain experience with the types of interactions and communication possible in various instructional contexts
- Develop a better understanding of the costs (capital and ongoing) and staffing requirements associated with distance learning applications
- Build the necessary compliment of equipment, instructional design expertise, and technical support required to provide the School with easy access to external environments via mid-cost distance learning equipment
- Develop an evaluation methodology for determining the efficacy of distance learning implementations

Technical Discussion

Once the instructional context of the project and the goals of the projects were understood, the project team entered a design and testing phase which focused on the analysis of various interaction scenarios and potential technical solutions.

Low end IP-based videoconferencing applications were considered (CUSeeMe/White Pine), but abandoned due to inadequate audio fidelity, poor video frame rates, and the unpredictability of service delivery over an open network (i.e. the Internet). Higher end satellite and T1/T3-based connections were also considered, but reluctantly ruled out due to financial considerations. After some investigation of mid-range videoconferencing tools (PictureTel, etc.), the project team chose ERIS from RSI Systems Inc. due to its mid-range cost, high quality audio, acceptable point-to-point ISDN video performance, and cross-platform capability. A demonstration system was procured from the local ERIS reseller (MiTech, Inc.) and ISDN lines were installed at each end of the connection.

After several frustrating attempts to resolve ISDN configuration problems, the first successful connection was made between Ann Arbor and Southfield. Once the connection was up and reproducable, the specifics of room setup, camera placement and micing could be considered. Although the configuration changes with the type of interaction planned, the typcial setup is shown in Figure 1.

As is indicated on the diagram below, the two rooms are linked via a 128K ISDN connection (2B+D) which covers the forty miles between the sites. The U-M site has two overhead microphones and two video cameras which pick up room audio and video from participants in Ann Arbor and relay it via ERIS to Southfield. There is also a FlexCam and microphone at the Macintosh workstation for private, face-to-face conversations. The ERIS software allows the various video inputs to be dynamically selected, while audio is routed through a mixer located at the workstation. Students typically face the front of the room where the remote image is projected onto a whiteboard surface. Remote audio is piped into a house audio system. The overhead mics and front-placed video cameras allow students to address the projected image as if speaking through a portal to Southfield.

BEST COPY AVAILABLE

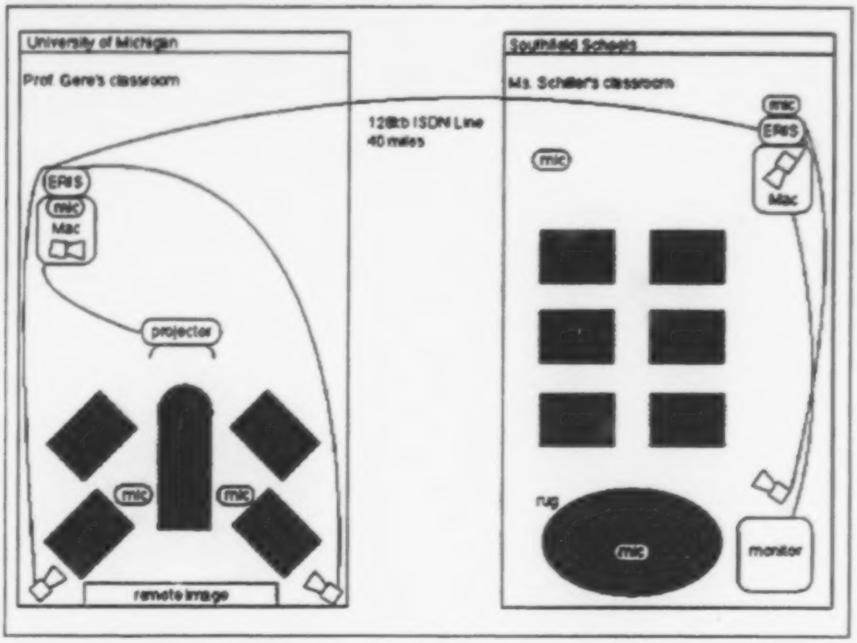

Figure 1: Diagram of TATE setup

The Southfield end of the connection is somewhat different. The ERIS, video cameras and mic equipment are similar, but the remote image is displayed on an overhead television monitor and the outgoing camera views are much more dynamic as a result of the shifting observational focus. The Southfield setup can provide face-to-face private conferencing (at the Macintosh station), small group observation (at the tables), large group observation (when students gather around the rug) and situated interviewing (when Ms. Schiller is standing at her desk at the back of the room discussing practice).

As implied above, the largest hurdle to be overcome in the technical arena was the installation and operation of the ISDN lines. These difficulties ranged from the ridiculous (trying to connect through the wrong jack) to the mystifying (telephone company line misconfigurations and communication gaps). Unfortunately our local phone company seems to have difficulty supporting ISDN, and so we offer to others seeking to use this technology some bits of advice:

- develop a strong personal relationship with a *responsive* person at your telephone company who will follow through on your order
- be sure you order and receive for each ISDN line:
  - an NT1 line terminator
  - a power supply for the NT1
  - any necessary adapters associated with your particular device
  - the correct line configuration (e.g. 2B+D) for your application
- be present when the line is installed and be sure you *see* the technician run a test on the line to confirm its operation
- get and record the following from your installer or representative *before* they leave:
  - your SPIDs (phone numbers)
  - your dialing prefix (if any)
  - your type of switch (e.g. Northern Telecom, AT&T)
- know where the line enters the building and comes into the room
- know what the installation and toll charges will be before installation

Some of these items seem ridiculously obvious, but our own experiences with a small army of technicians, many wasted hours and lots of stress recommend thorough preplanning and close

BEST COPY AVAILABLE

monitoring of the ISDN installation and configuration process. If your institution has dedicated telecommunications specialists it would be wise to include them in the planning process from the beginning.

Budget and Staffing

The budget for the project was roughly as follows:

Equipment costs:	
Audio-technica smartmixer	$500
microphones (5)	1400
ISDN installation - Ann Arbor	800
ISDN installation - Southfield	550
ERIS ISDN boxes (2)	8000
Tape stock (50 Hi8)	400
	$11650
Preexisting equipment*	
Hi8 video camera and tripod (4)	$8000
PowerMac 8500AV stations (2)	10000
Projection and audio system	variable; 4000 min.
FlexCam	400
	approx. $23000
Ongoing costs:	
ISDN toll charge - A2 to Southfield	.25/minute
Line charges - Ann Arbor	$30/month; $360 year
Line charges - Southfield	$36/month; $432 year

Table 1: TATE project budget

* These items were already owned by the School and so did not need to be purchased again for the project. It is fairly obvious however, that had these resources not existed, the cost of the project could easily have tripled.

The time investment from instructional design and support staff has been approximately 160 hours, roughly 40 of which were in direct support of live connections (the rest being devoted to designing, testing and troubleshooting). It should be noted however, that this figure includes neither Dr. Gere and Ms. Schiller's involvement, nor George Brackx' support investment. Were those hours to be included, the total would easily top 200 hours.

While the overall amount of cost and human resource investment is certainly significant, and perhaps daunting, it is expected that future implementations will not have to contend with the same ramp-up issues as the pilot. It is also hoped that lower cost technicians (e.g. graduate students) may be trained to deliver the live technical support necessary for successful use of the system.

Instructional Methodology

In all, the synchronous videoconferencing system was used in six discussion and observation sessions during the pilot program, for a total of about ten hours. Several different kinds of interactions and observations in support of preservice teachers acquiring a knowledge of practice were attempted:

Face to face exchange: Students were able to directly and privately communicate with their partners.

BEST COPY AVAILABLE

This connection was facilitated more in an attempt to get students comfortable with communicating over the link than to provide significant co-mentoring contact. The sessions tended to be quite short.

Small group observation: This observation scenario allowed University students to observe the outcomes of particular methods applications (e.g. self assessment by 6th graders). It also allowed for observation and discussion of peer interactions (i.e. grade student to grade student). Audio and video from a preselected set of students was delivered and subsequently discussed by Dr. Gere's students.

Large group to large group discussion and observation: During discussion, both groups were able to see, hear and speak with all participants. This type of discussion was difficult for the Southfield students however, because they could not resolve remote individuals in the relatively smaller display monitor. This problem was partially addressed by placing a remote video monitor in the group circle at the front of the room. As an observation tool it allowed University students to see classroom layout and management, and to get a sense of the overall classroom dynamics (noise levels, movement, etc.). The graininess of the ISDN bandwidth video disappointed some however, in that it made it difficult to clearly observe details of the remote activity. Audio, while overall very good, occasionally became loud as the activities in the remote room increased in amplitude.

Individual to group discussion (situated interview): Perhaps the most traditional application of distance learning technologies, this scenario was also the most technically successful (clear audio, good video, etc.). Ms. Schiller took questions from and discussed various aspects of practice with the U-M undergraduates while standing at her desk at the back of the room. However, as a vehicle for allowing observation of inter-student and classroom dynamics it was obviously appropriate. Most of the sessions began with this type of interaction then moved to one of the observation scenarios described above.

It should be understood that these divisions have been made relatively arbitrarily for the purpose of discussion. Despite the fact that the observational agenda was predefined, in actuality the observational flow of the connections was much more fluid than might be conveyed by the previous descriptions. This flexibility allowed for a relaxed approach to the interactions and a much quicker assimilation of the technology by the students than a more formalized approach might have encouraged.

Summary of Outcomes

There is relatively little that may be said in the way of summative evaluation immediately after the first semester of pilot use and data gathering. A more formal summative evaluation is being undertaken now by Dr. Gere and the project team. For the next semester the team will determine, through close analysis of captured videotape session data and student feedback and journals, the longer term efficacy of this particular distance learning technology in the area of preservice teacher preparation.

There is however, much of value that may be conveyed in the way of formative evaluation. Structured observation, student surveys, project team debriefs, and preliminary videotape screenings have strongly suggested the following opportunities for improvement:

- initial student orientation and expectation setting was inadequate (many students seemed to believe that the connections were intended to provide contact time with their partners as opposed to observation and practice discussion).
- initial faculty preparation and technical briefing was inadequate (this was partially due to the fact that our ISDN connection woes continued until the very last moment)
- initial communications protocols were inadequate (speech collisions were frequent and required uncomfortably long periods of time for recovery)
- determining appropriate lighting conditions was difficult and variable
- determining appropriate micing setup and levels (particularly in Southfield) was difficult
- students want better quality video than can be supplied over a 128K ISDN connection
- making students move to preestablished spots to ask questions decreased their tendency to interact and favored the extroverted students
- visibly reconfiguring the software and hardware during connections was extremely distracting
- development of a pre-connection checklist to ensure standardization of lighting, mic settings, software configuration, etc. would greatly reduce variability and increase confidence

There were also several fairly obvious successes:

- detailed preplanning of events (down to the minute in some cases) worked very well in ensuring smooth, transparent transitions from one observation or interaction to another
- students initially were highly engaged (perhaps overly) by the novelty of the approach and high technology in use, although this faded after the second session as the emphasis on the discussion of practice became more central
- other School of Education faculty have expressed an interest in using the technology
- audio quality was very good, and by informed standards the video was better than anticipated
- participants became more comfortable over time communicating via the link (collision frequency decreased and recovery time increased)
- having the initial use of the system include face-to-face videoconferencing with their partners greatly increased student engagement and reduced potential reluctance to communicate

As far as the instructional and institutional goals listed at the outset of this paper are concerned, the pilot met all of the stated goals (at least partially).

Instructionally it:

- provided preservice teachers with the opportunity to observe Ms. Schiller's class relatively unobtrusively (although the amount of that disruption is debatable)
- provided preservice teachers the opportunity to discuss practice with an exemplar teacher
- provided Dr. Gere and her students with a common observational frame of reference upon which to base discussion of teaching methodologies

From the perspective of the institution it:

- helped us gain a better understanding of the capabilities of emerging distance learning technologies and precipitated the gaining of experience with the types of interactions and communication possible in various instructional contexts
- helped us develop a better understanding of the costs (capital and ongoing) and staffing requirements associated with distance learning applications (the ongoing technical support needs in particular are not as low as could be desired)
- precipitated the specification and acquisition of the necessary compliment of equipment, instructional design and technical support required to provide the School with easy access to external environments via mid-cost distance learning equipment
- did not require that we develop an evaluation methodology for determining the efficacy of distance learning implementations (although it is anticipated that the summative evaluation worked being done will address this need)

Naturally, such an ambitious and successful pilot project has inevitably lead to even more ambitious goals (some of which are outlined in the next section). In light of this development, additional funding has been sought from various sources including the U-M Whitaker fund and FIPSE grants.

Next Steps

Briefly, here are some of the applications and improvements that we are intending to investigate as the technology matures and is used by more faculty in support of similar instructional objectives:

- install additional ISDN lines and multiplex them to increase bandwidth available for video as well as to provide for the monitoring of both ends of a connection on-site for troubleshooting and design purposes
- incorporate shared window and whiteboard applications
- incorporate the use of a Visualizer video feed for transmitting object images and scans of grade school work on the fly
- incorporate asynchronous technologies (e.g. web, email) to support offline communication between student pairs
- attempt the inclusion of additional support staff (e.g. graduate students, previous participants) to reduce the cost and strain on current support resources

Cyberspace Needs A Devil
Accreditation for Cyberspace Documents: A Proposal

Russell F. Dennison
Library Department
Winona State University
USA
rdennison@winona.msus.edu

Abstract: Locating trustworthy quality information in cyberspace is becoming increasing difficult due to the increase in vanity publishing. Attempts to solve this problem must address the authority of cyberdocuments as well as information retrieval methods. It is proposed that an accrediting agency be created by academic institutions. This agency would provide a quality filter and permit the restriction of information searches to documents that have been accredited. A major advantage would be the ready availability of scholarly information to everyone, not just people with access to a research university libraries. The cost of creating and maintaining such a process could be recovered by the replacement of ever-more expensive paper journals with review e-journals.

The Problem

Education has been defined as a student, a teacher and a book. Distance and networked education in combination with cyberspace resources change the location and definition of "book." Educators need to consider changes in how students locate and retrieve information.

Quality information is vital. As a researcher, I depend upon locating high quality information quickly. As an academic librarian, other people depend upon my help in locating high quality information quickly. Networks and network tools like Archie, Gopher, and Netscape have greatly increased my ability to locate information. However I have noticed that the amount and type of information available over the networks has changed over the last few years, making it harder in several ways to find scholarly information. There is more total information available, therefore it is harder to find any one item of information. There is no overall organization by subject matter. There is an increasing amount of "vanity" publishing going on, especially on the WWW. Other researchers have found these problems too.

The increase in amount of information is not necessarily a critical problem. Organization can overcome volume in cyberspace, just as it can within a major research library. However that organization is not present. Clifford Stoll wrote, "New Internet users often blame themselves for not being able to find information...They don't realize the disorganization of the network is the root of their troubles."[Stoll 1995] Demas, McDonald and Lawrence point out that "what many Internet users are demanding is the kind of selection and organization that libraries have traditionally brought to the world of published information resources."[Demas et al 1995] Michael Gorman confirms this with the observation that "'Surfing' is the process of sifting though this disorganized mess in the hope of coming across some useful fragments of text and images that can be related to other fragments."[Gorman 1995] Clifford Lynch wrote "In short, the Net is not a digital library. But if it is to continue to grow and thrive as a new means of communication, something very much like traditional library services will be needed to organize, access and preserve networked information." [Lynch 1997]

Besides the lack of organization, there is the problem of vanity publishing. One of the problems caused by the increasing numbers of cyberspace users and the increasing ease of publishing in cyberspace is the increasing amount of trivial or erroneous information in cyberspace. Trivial or erroneous information wastes both bandwidth and time. Poor quality documents are not just irritants but time-wasters and therefore money-wasters.

Many of these poor documents in cyberspace are simple vanity items. Formerly the cost of publishing in print on paper served as a partial barrier to vanity publishing. The traditional scholarly communication pattern also served as a barrier through the use of peer review and editorial control. However the cost and the control are not present in cyberspace, except for certain areas.

Publishing used to be an expensive matter. If one wanted to nationally or internationally distribute a flyer or pamphlet, one had to spent a considerable amount of money. The cost of publishing on-line is much lower. Webpages are easy to create and change. This has allowed thousands of people to become their own publisher.

Many of these personal webpages are interesting. However when one is searching for information on-line, these webpages can become time-wasters. Even if a webpage is relevant to a search, the question of authority is unresolved. For most webpages (or even most cyberspace documents), there is no readily apparent means to evaluate the accuracy of the information presented. E-journals share this problem, whether they are peer-reviewed or not. Cyberdocuments lack authority.

Michael Gorman also wrote "Computerization makes quality records easier to use and makes new ways of using them possible; it does not eliminate the need for that quality."[Gorman 1995] Thomas Mann agrees, " If a system makes only *some* sources easily available--especially if those sources are very superficial or of poor quality--then it can do real damage to the quality of research, for it will encourage users simply to make do with whatever sources are *readily retrievable*, regardless of their quality or completeness."[Mann 1993]

Some people wonder if cyberspace is an overblown promise. Robert Raskin wrote, "It's a misinformation highway...The democratization of information means that everyone has the right to be an authority...It's inefficient...With today's proliferation of on-line information, finding what you want is nothing short of a major victory."[Raskin 1994] Other people, like Langdon Winner, argue that these problems should be solved. '"Beyond today's fascination with 'cool sites' lies the need to create tools for inquiry that favor intelligence over confusion and absurd spectacles."[Winner 1995]

Attempted Solutions

One of the main problems of information retrieval is recall versus accuracy. Many information retrieval experts feel that there is a fairly strong reverse relationship between recall and accuracy. That is, as recall increases, relevancy decreases. As recall decreases, relevancy increases.

Recall is the amount of relevant items found as compared with the amount of possibly relevant items. In an uncontrolled system like the Net, it is impossible to know the amount of possibly relevant items. The most usual attempt to increase recall is to broad search strategies.

Accuracy is the relevancy the results. Most items discovered by use of search engines are not very relevant to the user's information need. When confronted by a long list of references, most users do not explore beyond the first 30-35 items.[Wiberley 1995] When search engines produce 50,000+ "relevant" items, users do not usually examine one tenth of one percent. Therefore adding more items from different search engines will probably not improve the relevancy, but it will probable obscure relevant items but placing less relevant items earlier on the list.

There are many attempts to organize or maximize information retrieval processes. Most search engines have many advanced capabilities such as boolean logic. These advanced capabilities require advanced knowledge of the user coupled with continued practice. Unfortunately each search engine seems to have either different capabilities or different syntax for its capabilities. This makes it difficult for a user to be a skilled user of many search engines. However since the databases of different search engines usually seem to be only partially overlapping, some users prefer to use multiple search engines for important searches.

Meta-search engines are being used to allow a search string to be entered at one location, but be searched by many search engines. Since the meta-engines do not permit the use of advanced capabilities, this merely plays to the lowest common denominator. The result is many results, but lower accuracy.

Directories are popular as well. Directories are created by people rather than programs. Each item in a directory should have been reviewed by a person who assigned a subject heading(s). This makes for much more accurate results. The major disadvantage of a directory is the small size, because a directory is very labor intensive.

BEST COPY AVAILABLE

Collaborative filtering uses human feedback and profiles to recommend items to a user. This is based on the use of reviews and the concept of community of interest. Two of the better known projects are GroupLens (http://www.cs.umn.edu/Research/GroupLens/grouplens.html) and Firefly (http://www.agentsinc.com/About1.html). These require an adjustment time to create a profile before the collaborative filtering becomes effective. This also filters out "dissenting" or "differing" point-of-views. Firefly describes collaborative filtering as "word-of-mouth on a global scale." A fair comparison might be to Nielsen or Arbitron ratings for information.

OCLC is conducting an Internet Cataloging Project (InterCat). This is an attempt to have professional librarians catalog cyberdocuments to "create, implement, test, and evaluate a searchable database of USMARC format bibliographic records, complete with electronic location and access information for Internet-accessible materials."[OCLC 1996] This is rather like a directory created by librarians. It is a high quality and reliable directory. However it is small when compared with the Net and is constantly shrinking as a percentage of all cyberdocuments. That is, the size of the net is increasing faster than the size of the InterCat (OCLC's NetFirst http://www.oclc.org/oclc/netfirst/netfirst.htm, which includes all InterCat records and more, is adding about 8,000 records a month while the WWW is growing at about one million pages per month).

PICS, Platform for Internet Content Selection (htp://www.w3.org/pub/WWW/PICS/iacwcv2.htm) has established labeling specifications for cyberdocuments. Labels can be assigned by anyone to any document, however a searcher must use the database that holds the labels. These labels can be used for filtering purposes. Currently much of the attention devoted to PICS seems to center on limiting or blocking access for children.

A Proposal

A possible solution lies in a parallel situation. When there were few universities, accreditation did not exist. The few institutions were known to their audiences. Once there were many universities, it became impossible for the average person to know the reputation, orientation, or quality of every or even most institutions. Therefore accreditation arose as a way of certifying a minimum level of quality.

Accreditation is done by a voluntary association. The members of the association have promised to meet certain minimum quality standards. There is an initial inspection to determine that certain minimum levels of quality are being met. Thereafter the individual members of the association are the continual judges of their own quality. However there is also a periodic inspection by a team representing the entire association. This inspection either validates the individual member's judgment of continuing quality or the inspection documents deficiencies that must be corrected for the member to remain in the association, that is, to remain accredited.

Electronic document accreditation could follow the same pattern. A site that desires to have its documents accredited would apply to the association for membership. An inspection team would evaluate the prospective member's documents being put forward for accreditation. If the documents are of satisfactory nature, then the site would be accepted into the association.

The local site would be then responsible for the individual certification of its documents. This certification would be shown by the addition of a trademark (perhaps in a PICS label) to the document. It would be expected that many or most documents would not be certified (such as school calendars, phone books, faculty directories, etc.), only those that are intended as quality, reliable scholarly or educational materials, perhaps at the level one would expect to find in an academic library.

At regular intervals, the association would have an inspection team review a representative number of documents from an accredited site for re-accreditation purposes. If a site lost accreditation, then the trademark would have to be removed from all of the site's documents.

Although the primary advantage to accreditation would be quality assurance of documents in cyberspace, another advantage would be that the trademark could be searchable. This would permit the use of the trademark as a search limiter. That way, someone searching cyberspace would waste less time in information retrieval due to retrieving poor quality documents. Alternately, the search engines could restrict themselves to searching only accredited documents. For example, Lycos (or any other search engine) could offer accredited documents as an optional database for searching.

The obvious mechanism for electronic document accreditation is an association of higher education institutions, although scholarly societies, associations and foundations could also readily be involved. Cyberdocument accreditation would be an additional duty and require additional work for a university, but the benefits to the scholarly community would be great. In fact, if electronic document accreditation is successfully implemented, several accreditation agencies may have to come into existence to cater to specialized needs or subject matters. Fortunately the cost of accreditation visits would be greatly reduced, since the visits could be electronic not geographic. There would also be less cost in preparing reports, since all the material to be evaluated is available in electronic form.

The primary reason for accreditation would be to certify quality by having not just an author, but an association of universities attest to that quality. However this could solve another large problem plaguing higher education. The rising cost of serials has been called the "library doomsday machine" by *Publishers Weekly*. The cost of journal subscriptions has risen greatly over the last two decades. Elsevier (one of the largest science publishers in the world) had a 23.9% price increase for American subscriptions last year. Most university libraries have had to "downsize" their subscriptions over the last ten years.

Electronic journals have been suggested by some as the solution to the increasing serials prices. These e-journals are usually e-mailed to subscribers or placed onto webpages for subscribers to access. However even though some e-journals are peer reviewed, the prestige associated with publishing in an e-journal has remained low. Until the e-journal has more recognized authority, it will remain a less prestigious member of the scholar communication process. Obvious the lower prestige will limit the use and potential of e-journals. However if a university were willing to accredit an e-journal, especially if the university were prestigious, then that e-journal might also acquire a more favorable recognition. This legitimacy could increase the use of e-journals by authors, researchers and students. A shift to e-journals could thus perhaps reduce the scholarly reliance on traditional print-on-paper journals that are rapidly increasing in price.

The creation of an accrediting association would be difficult, but if done successfully would confer great prestige and recognition on the initial innovators. Quality assurance of documents would be of world-wide interest and impact. Legitimacy of e-journals could reduce the costs of research and scholarly communication.

Why does cyberspace need a devil? Accreditation has almost always been controversial. In 1939 Samuel P. Capen delivered a speech against accreditation entitled "Seven Devils in Exchange for One." The speech was on the exchange of local control for accreditation. Perhaps the devil of electronic document accreditation is a preferable choice to the deep blue sea of vanity publishing in cyberspace?

Abstract

The development of educational software is a difficult and time consuming task. One of the main reasons is that design methods seldom fit to a specific design problem and therefore developers rarely use these methods. We describe the 'Situated Model-Based Development Approach of Educational Software' as a possible answer to this unfit. Situated means here that this approach enables developers to set up a design approach for individual educational software design problems. A resulting design approach is tuned to characteristics of an initial design problem and project context. Model-Based means here that we see models as tentative solutions to educational software design problems. We expect that the application of this approach will lead to less difficult and less time consuming development of educational software. In addition we expect that research on this approach will help us to gain further insight into design issues of educational software.

Introduction

The development of educational software is a difficult and time consuming task, although developers of such systems have at their disposal a variety of design methods, authoring tools and environments. One of the main reasons is that developers of educational software still see the development process mainly as a creative ones, in which existing design methodologies only offer limited support and therefore are rarely used. As a result however, development processes are difficult to manage and resulting educational software lacks, for instance, quality, opportunities for maintenance, and re-use of software parts.

The field of Software Engineering encountered similar problems while developing information systems. An answer was found in a development approach named 'Situated Model-Based Development of Information Systems'. We think that this approach can also be applied to the development of educational software. In this paper we describe an example of a Situated Model-Based Development Approach. We will not describe however extended rationales behind this approach. These rationales are discussed in more detail by, for instance, Harmsen, Brinkkemper, & Oei (1994), van Slooten (1995), and Lemmen, Brinkkemper, & van der Veen (In preparation). Finally, we discuss implications of applying such an approach for the development of educational software and for design aspects of this software.

To make our discussion more concrete, we want to restrict it to a specific type of educational software. Educational software refers to a variety of software products, names of which are composed of several subconcepts referring, for instance, to:

- an interesting aspect of a product, such as: Interactive, Flexible, Integrated, Performance, Multimedia, Distance, Telecommunication, Virtual;

- an educational aspect of a product, such as: Assisted, Learning, Training, Support, Instruction, Training, Study, Course, Classroom, Education;
- a software or hardware aspect of a product, such as: Tool, Program, System, Environment, Card, Computer, Network.

Names are for example an Interactive Learning Program or a Virtual Course Network.

The specific type of educational software we refer to is named Interactive Study System (ISS) (de Vries, Vogel & Brinkkemper, 1997). Interactive is stressed, because we consider interaction as one of the main advantages of the use of computers for instructional purposes. Study is meant in the sense of 'to spend time in learning' and also in the sense of 'a room used for studying and working'. We want to emphasize flexibility of users in the study process while 'spending time in learning in the interactive room'. A study process can be described as an interaction process among a teacher(s), a student(s), and information content, which process is mediated by an ISS. System refers to a software product meant for a specific set of user tasks, for instance a word processor or a spreadsheet. Basically we see an ISS as a software system consisting of study tools, educational resources, and if needed additional materials. An ISS can be extended by generic software tools, like communication and information editing tools. Study tools can vary from drill and practice tools, tutorial tools, simulation tools, concept mapping tools, study workplaces, etc. Study tools are software tools that are particularly designed to enhance individual or group-based study processes. Educational resources refer to the multimedia information content matter. Additional materials refer to information and/or tools that support study processes but which are not offered in an electronic way. Generic software tools are tools that are not particularly designed to enhance study processes. Examples of such tools are communication and information editing tools. Communication tools can be used to enable communication among students, among student(s) and instructional managers, and information providers, etc. Information editing tools can be used to edit documents, spreadsheets, tables, e.g. The main goal of an ISS is to enable an interactive study process between a user of the system and other users and/or between a user(s) and educational resources.

In this paper, we present a Situated Model-Based Development Approach of ISS's . 'Situated means here that this development approach enables developers to set up a design approach for individual ISS design problems. A resulting design approach is tuned to characteristics of an initial design problem and project context. 'Model-Based' means here that we see models as tentative solutions to ISS design problems.

Situated Development of Interactive Study Systems

The Situated Model-Based Development Approach we apply in this paper is based on Lemmen & Punter (1994a & 1994b). Their approach is meant for the design of Information Systems. We have transferred and simplified their approach in order to apply it to the design of ISS's. This transferred and simplified model is presented in Fig. 1.

A framework for modelling ISS's is the core of this Situated Model-Based Development Approach. Several approaches are used in Software Engineering in order to represent information systems. The approach Lemmen & Punter have chosen, is MADIS, a Modelling Approach for Designing Information Systems (Essink, 1986; Essink, 1988). The leading idea behind this approach is that modelling of information systems always takes place on different levels of abstraction, but on each level the same modelling aspects come up. According to Lemmen, Brinkkemper & van der Veen (In preparation) as this approach is based on experiences in a variety of design projects, the resulting framework is very compact and complete. As ISS's can be regarded as a specific type of information systems, we think that the MADIS approach is applicable to modelling of ISS's.

Interactive Study System Design Approach

Figure 1 Situated Model-Based Development Approach for Interactive Study Systems

It has been already mentioned, MADIS deals with modelling levels and aspects. There are four modelling levels identified: the object system modelling level, the conceptual interactive study system modelling level, the data system modelling level, and the implementation modelling level.

- The object system modelling (OSM) level is the level where a description of that part of an organisation for which an ISS should be designed and realised is given. Such an organisational part can, for example, be a Training Department of a large company. This department provides employees with continuing training opportunities by applying ISS's in order to enable them to study at home using the Internet.
- The conceptual interactive study system modelling (CISM) level is the level where the ISS is viewed as a set of (functional) components, which enables the users to attain the study goals. In the example of a Training Department such an ISS can consist of several components. An employee at home may have an Employee Student Study System including Internet Communication Tools. A Training Department may have an Educational WebSite consisting of Training Information Content and on-line educational support tools.
- The data system modelling (DSM) is the level where an ISS is considered to be a data processing system. The main issue here is how an ISS works. In our example a description is given, for instance, of the Training Information Content, the intended communication procedures between the WebSite and employees, and the intended study interaction processes.
- The implementation modelling (IPM) level is the level where an ISS is viewed as a concrete, operative and maintainable system, which has to be developed, used, and maintained in a user context, for instance, at a Training Department and at homes of employees. An implementation model can be viewed as a blueprint of a yet to be developed ISS. In our example choices have to be made for instance for a specific WebBrowser, database system, study tools, and hardware configurations.

At each modelling level a distinction is made among eight modelling aspects. These aspects are: Goal structure, Environmental interaction, Functional structure, Entity structure, Process structure, System dynamics, Allocation aspect, and Realisation aspect. Each aspect can be considered as a modelling view on ISS's.

- A goal structure view implies that an ISS is an organised set of elements and relationships between them, directed at the realisation of a set of study goals.
- An environmental interaction view implies that most ISS's have a dynamic reality whereby external active elements have an impact on these systems because of their behaviour.
- A functional structure view implies that an ISS can be decomposed into subsystems or modules until a level of decomposition is reached at which, in terms of the problem at hand, it is no longer meaningful to identify smaller modules.

BEST COPY AVAILABLE

- An entity structure view implies that an ISS can be decomposed into relevant entities, their properties, and their relationships. Entities can be viewed as passive elements in a system whose status is a result of the behaviour of active modules determined in the functional structure.
- A process structure view implies that an ISS has a structure and a process. In each functional module processes take place as part of the study process as well as of the management process of the ISS.
- A system dynamics' view implies that the behaviour of the ISS should be specified in a time dimension in order to be able to verify how it corresponds with the reality.
- An allocation view implies that there is a need for matching personnel and equipment with the requirements and demands, which are needed to perform the study processes in the organisation. In other words, a design of a ISS is not complete without results of an organisational and technical feasibility analysis.
- A realisation view implies that an overview of consequences of a design process is needed in terms of personnel, equipment, software, etc. Its main purpose is to reveal the demands that a design of an ISS puts on an organisation.

Taking into consideration, this description of levels and aspects it is possible to set up a framework for modelling ISS. This framework is presented in Fig. 2.

	Goal-structure	Environmental interaction	Functional structure	Entity structure	Process structure	System dynamics	Allocation aspect	Realisation aspect
OSM								
CISM								
DSM								
IPM								

Figure 2 **A framework for modelling Interactive Study Systems**

Each element of the framework describes a modelling area using an aspect of an ISS on a certain modelling level. We assume here that these 32 elements give a rather complete overview of relevant ISS-modelling areas. The description consists of modelling specifications, basically of modelling questions. Modelling questions for the element OSM/Goal structure are for instance: What are the goals of the organisation in which the intended ISS is going to be used and what is the desired contribution of the intended ISS to the attainment of these goals? Answering all the relevant modelling questions on a specific ISS should eventually lead to an actual model of that ISS, which should be looked upon at a tentative solution to the initial ISS design problem.

However, in order to answer all such questions, there is a need for design methods, techniques and instruments. To meet this need, Lemmen & Punter use the concept Method fragments. Method fragments are design methods and/or techniques stemming from existing information system design methodologies, which are applicable in generic partial design problems. Lemmen & Punter assume that all such method fragments can be represented in the framework for modelling information systems. The result of this representation is a Method Fragment Base, which is a database filled with method fragments, structured according to the framework for modelling information systems. Instead of information systems, we speak of ISS's. That implies that based on the presented framework for modelling ISS's, we have to represent method fragments stemming from educational software design methodologies in order to realise an Method Fragment Base for ISS's.

This Method Fragment Base can be used as a source for method fragments. This can be done by representing an initial ISS design problem on the framework for modelling Interactive Study Systems. This implies that an initial problem is splitted upto modelling areas. For each modelling area a choice has to be made for one or more method fragments. This process of deriving and fine-tuning of appropriate fragments is called Matching. The result of Matching is a Situated Interactive Study System Design Approach. It is situated, because the fragments chosen are based on characteristics of the initial ISS design problem. The approach is model-based because the final results of this approach are tentative models of the intended ISS. The whole approach is adaptable. For instance, developers can add their own modelling aspects, modelling questions or method fragments to the approach.

The above description of a Situated Model-Based Development Approach for ISS's is simple, as only the main ideas behind this approach are outlined. An important issue in our further research is

BEST COPY AVAILABLE

to reconsider the modelling aspects and to conceptualize educational software modelling aspects. We are for instance transforming characteristics of educational software – such as quality and practicality of use -- which are held responsible for the succes of implementation of educational software in curricula into such aspects.

Discussion

The final issue to be adressed here is, may we expect that application of this Situated Model-Based Development Approach for ISS's leads to less difficult and less time consuming development of such systems?

We consider two reasons to expect that an answer to this question is of positive nature. First, this approach forces developers of ISS's to think of and to construct a design approach in the earlier stages of a development process and the resulting approach is expected to fit to characteristics of the initial ISS design problem and project context. Secondly, this approach provides designers with appropriate design experiences. The framework for modelling ISS's can be considered as an ISS Knowledge Base and a Method Fragment Base as a Design Knowledge Base. Adaptation of both, the framework and the Method Fragment Base, makes it possible to continuously accumulate experience. As a result the development of ISS's is expected to become less difficult and time consuming.

However a less difficult and time consuming development of ISS's is not the only promise of applying this Situated Model-Based Development Approach. We think that research on this approach will help us to gain insight into design of ISS's and therefore educational software in general. Elaboration on the eight modelling aspects is one of the research issues. A further specification of, for instance, modelling questions for all four modelling levels will help us to improve our understanding of relevant design aspects of ISS's. Another research issue to be considered is the Method Fragment Base for ISS's. Creating such a base implies a thorough analysis of the relevance of methodologies to the design of ISS's. Representing existing method fragments onto the framework for modelling ISS's will lead, for instance, to insight in the omission or inadequacy of fragments for specific modelling area's. We think that further research into this Situated Model-Based Development Approach of ISS's will lead to a growing insight in the design (product and process) of educational software.

Abstract. In this article we present the design of HyperMed, an educational hypermedia application conceived to teach undergraduate medicine students, using the Labyrinth formal model whose main advantages are the inclusion of users modelling and the possibility of defining generalised structures and security policies. HyperMed allows students to treat a series of "patients" presenting different symptoms. The characteristics of the model and the functionality of the educational application are briefly exposed, the design of the application is outlined and the conclusions derived from this experience are also presented

Introduction

Hypermedia systems differ from other software applications in critical issues, such as the inclusion of different kinds of reactive and dynamic information and their sophisticated behaviour in navigation. Due to these special features, traditional design models and methodologies are not well suited for hypermedia design [Fuller et al. 1992; Garzotto et al. 1993] and for this reason dedicated formal models have been developed. Trellis [Stotts and Furuta 1989a,b] for hypertext and Dexter/Amsterdam [Halasz and Schwartz 1990; Hardman et al. 1993] for hypermedia systems are widely diffused ones. Although these models fulfil hypermedia requirements, like structure-content distinction, definition of anchors and composite elements, time-based relations, etc., important issues still remain not addressed. For example, in Trellis, virtual anchors and links to represent semantic relationships are not included; aggregation and generalisation relationship are not modelled and mechanisms to guarantee information integrity cannot be defined. Dexter/Amsterdam do not allow dangling links nor links representing different semantic relationships; generalisations can not be defined; conditional synchronisations for multimedia information are not allowed and security mechanisms cannot be modelled.

Labyrinth [Díaz et al. 1996a] is an abstract model that do fulfil the above mentioned requirements as well as those of the third generation of hypermedia systems described in [Halasz 1988]. The most salient features of Labyrinth are:

- It makes a clear distinction between the abstract containers that make up the hyperdocument structure (modelled by means of the nodes) and the information items (modelled by means of the contents).
- Link and anchor definitions allow several types of uni- or bi-directional links to be defined. Dangling, virtual and context links as well as semantically different relations can also be defined.
- Composite nodes are used to represent the generalisation and aggregation abstractions defined in [Garg 1988] by means of multitarget links. Both mechanisms define composite nodes that structure the system on a logical and operational level. Aggregation composite nodes allow to refer to a group of nodes by means of a unique identifier, regardless of the properties of the nodes. Generalisation composite nodes provides a means to represent a set of nodes sharing at least one hereditary

characteristic. Common characteristics are defined in the composite node and are inherited by each generalised node. Complex structures can be represented by nesting several composition levels.

- The definition of temporal dimensions in Labyrinth permits multimedia information and timing to be explicitly treated. Events are defined as expressions that state the conditions under which a series of actions are triggered.
- Different access mechanisms such as queries or browsers can be defined.
- Labyrinth allows users to define personalisations by adapting the contents and the structure of the hypermedia net to their needs and preferences. Personalisations do not affect the basic document and are visible only to their owners (groups or individual users).
- Two security mechanisms are included: a discretionary mechanism preserves information confidentiality while a mandatory one, based on classic flow information models, ensures information integrity.
- Elements for version control are provided, allowing unlimited version sequences of nodes and contents to be maintained.

In this article, we present an example of the use of Labyrinth for the design of generalisations in hypermedia structures and the definition of security policies, by describing the design of an educational hypermedia application, conceived to teach undergraduate medicine students. Only the model components used in this example are formally defined here.

The Labyrinth model

In Labyrinth, a hyperdocument is defined as the union of a "Basic Hyperdocument" and a series of "Personalised Hyperdocuments", each of them belonging to a user or group of users. In a personalised hyperdocument, users can either modify components of the "Basic Hyperdocument" adapting them to their own necessities or create new ones. The "Basic Hyperdocument" consists of the following 11-tuple:

$$< U, N, C, A, L, B, E, lo, al, el, ac >$$

where "U", "N", "C, "A", "L", "B" and "E" are respectively sets of Users, Nodes, Contents, Anchors, Links, attriButes and Events and "lo", "al", "el" and "ac" are functions. "lo" determines the location of a content into a node, "al", "el" and "ac" get the list of attributes, the list of events and the access category of an element respectively. In addition, each user or users group can have a "Personalised Hyperdocument," that is defined using the following 10-tuple:

$$< UserId, N^P, C^P, A^P, L^P, B^P, E^P, lo^P, al^P, el^P >$$

where "UserId" is the User identifier indicating the owner of the personalisation (group or individual) and the remaining items are personalisations of some items defined in the Basic Hyperdocument tuple. "N^P", "C^P", "A^P", "L^P", "B^P" and "E^P" are either composed by new elements or modifications of the corresponding components of the Basic Hyperdocument. "lo^P", "al^P" and "el^P" are also composed by new or modified functions.

The formal definition of some of the model components and, in particular, those used in the example of the next section, are included in [Tab. 1] .

HyperMed Design

In this section, we present the HyperMed application, then, its design and, finally, the advantages of the Labyrinth model use are shown. The most relevant benefits of using the model can be summarised as the potentiality of:

- defining types of users depending on their roles and abilities;
- specifying the application structure from a logical point of view, and
- defining a security policy during the design stage.

Application Description

HyperMed is an educational tool intended to help undergraduate medicine students to analyse real cases. With this purpose, students, who are supervised by teachers, will be able to treat a series of "patients" who present

BEST COPY AVAILABLE

different symptoms. Every patient has a card with his/her clinical history (symptoms, treatment, tests' results and other relevant data). For each type of test, all data are held in order to study the reaction of the patient to a particular treatment.

HyperMed students are organised in groups. Each group is concerned with a medical speciality, and it takes care of its own patients. Group members can discuss and take decisions about a treatment, as well as modify the card of a patient. In order to identify a pathology or treatment, students can inspect a common theoretic repository where information for each illness is provided. In addition, students can consult but not modify the patient cards which belong to other groups, since they can not take part in their treatment.

Teachers are responsible for students' groups, and, therefore, each teacher can browse and add notes to the cases treated by the members of the group he is surveying. They can also modify the contents of the theoretical repository.

HyperMed is conceived as a hypermedia system. A hypertextual structure is used to provide a direct access to related terms and concepts. Multimedia contents, like text (e.g. blood analysis), images (e.g., radiography), video (e.g., colonoscopy) and sound (e.g., pulse), are used to enrich the information about patients and pathologies.

Design Description

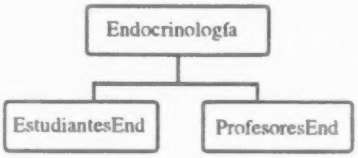
Labyrinth has been used to carry out the design of HyperMed which has been divided into the following tasks:

- Definition of users
- Definition of the hyperdocument structure
- Inclusion of contents
- Definition of the security policy

The use of the model in each task is described below, highlighting those aspects for which Labyrinth was found more useful. A graphical representation of the model components is used in some tasks to illustrate the formal definition.

Definition of the Users. From the description of the application, the existence of different kinds of users, with distinct abilities to manipulate information, emerges as an essential characteristic of the system. Labyrinth users provide a formal way to specify this characteristic during the design stage.

In particular, two different groups of users are considered for each medical speciality: students and teachers. Constraints are not imposed on the groups definition and, therefore, individual users can take part in different specialities and play different roles depending on the group they are included. For example, [Fig. 1] shows the definition of the users' groups for the "Endocrinología" speciality.



```
("Endocrinología", group, {"EstudiantesEnd","ProfesoresEnd"})
("EstudiantesEnd",group,{StudentEnd1,...,StudentEndN})
    where StudentEndI (I=1,...,N) is defined as an individual user
("ProfesoresEnd",group,{TeacherEnd1,...,TeacherEndN})
    where TeacherEndI (I=1,...,N) is defined as an individual user
```

Figure 1: Example of users definition

Each group of users is assigned an ability to manipulate the hyperdocument in the definition of the security policy.

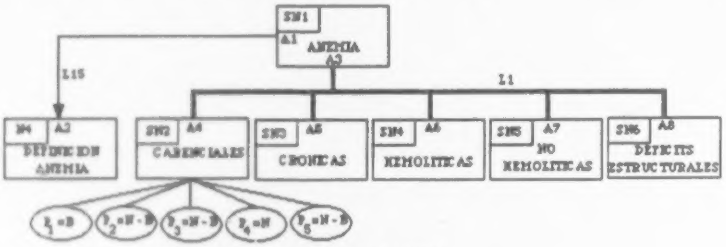
Definition of the Hyperdocument structure. The information of HyperMed, can be conceptually organised using hierarchical structures with or without heritage of characteristics. Aggregation and generalisation mechanisms provided by Labyrinth can be quite useful to define the structural components of the system. In this task, a network of nodes and composite nodes, connected by aggregation and generalisation links, is used to conceptually define the system structure. In addition, referential links are used to define navigation paths.

For example, [Fig. 2] shows an example of the structure corresponding to the "Anemia" pathology included in the theoretical repository. In the figure, the different kinds of this pathology (e.g. nutritional, haemolytic, aplastic..) are generalised by means of a composite node (SN1) and the general link L1. The general node includes a referential link to the definition of this illness (L15) which will be inherited by all the generalised nodes. Other elements included in this structure are the attributes (PI) which add semantic information to the elements. For example P1 represents low levels of red blood cells which constitutes a symptom of nutritional anaemia.



(L1,{A3}, {A4, A5, A6, A7, A8})
AL(L1)={(Direction, bi),{TypeLink,General)...}
(A3,SN1,-1,(-1,-1))
(A4,SN2,-1,(-1,-1))
(A3,SN3,-1,(-1,-1))
(A3,SN4,-1,(-1,-1))
(A3,SN5",-1,(-1,-1))

Figure 2: Hyperdocument structure example

Inclusion of the Contents. The hyperdocument structure is thoroughly specified by defining the contents that are included in each node and composite node. Contents are placed in the spatial and temporal axis of nodes and composites. Synchronisations and space-based relationships are also defined among contents.

Definition of security policy. The security policy is defined by means of the security labels provided by the Labyrinth model, whose value can be set to "editing", "browsing" or "personalising".

Users defined in the first task are assigned a security label which determine their ability to manipulate the system elements. For each medical speciality, teachers are allowed to modify the theoretic contents and to browse and add comments to the student works. For example, the value of the access function ("ac") of "ProfesoresEnd" and node "PacienteEndocrino" in [Fig. 3] is set to "personalising", so that a teacher of this group is avoided to edit the contents of this node, whereas they have an "editing" category for the node "DefiniciónCarencial" which represents an entry of the theoretical repository. Students can personalise and modify the cards of their patients (see the value assigned to the group "EstudiantesEnd" for the node "PacienteEndocrino"). Moreover, all students are allowed to browse the theoretical contents and the patient cards belonging to other groups.

ac ("ProfesoresEnd", "PacienteEndocrino",personalising)
ac ("ProfesoresEnd", "DefiniciónCarencial", editing)
ac ("EstudiantesEnd","PacienteEndocrino",editing)
where:
"PacienteEndocrino" represents the card of a patient who presents anaemia symptoms

Figure 3: Example of security policy specification

BEST COPY AVAILABLE

Security labels are also tied to nodes, composite nodes and contents to restrict the operations which can be performed over them. Most of them have an "editing" category which will can be constrained by testing the user's category.

Conclusions

A number of advantages have been derived from the use of the Labyrinth model in the design of HyperMed, in agreement with previous experiences in the design of applications with this model [Díaz and Aedo 1996].

The most important conclusion is that the use of Labyrinth allows to unambiguously define the system, providing a communication channel between the different members of the development team. In particular, the definition of user groups, the hyperdocument structure and security requirements during the design stage, have been found quite useful to reduce unexpected problems and requirements.

The output of the design phase has been a clear hypertextual structure where aggregations and generalisations were used to organise hierarchical trees of illnesses. In addition, the distinction between contents and nodes allowed to avoid duplication of documents and redundancy of information. The roles and abilities of the users were defined by means of the mandatory security policies included in Labyrinth. The use of version links permitted to maintain the sequences of tests in ordet to analyse the evolution of the symptoms.

Although the up to now experiences are very encouraging, the limited number of applications designed with Labyrinth does not permit a precise evaluation of the capabilities and limits of the model. With this purpose, the design of more complex hypermedia applications for distributed and collaborative environments is needed.

Moreover, two factors, the design quality (in terms of accuracy and comprehensiveness) and the time required to complete it, were shown to be strongly dependent on the skills and previous knowledge of the designer about hypermedia systems and models. To solve this weakness a detailed design methodology is required and, in fact, it is already under development [Díaz et al. 1996b].

Problem Based Learning:
A Means to Evaluate Multimedia Courseware in Science and Technology in Society

Mike Dobson
Faculty Fellow Program for Advanced Learning Systems
University of Calgary, Canada

Abstract: Multimedia learning materials for the grade 11 and 12 chemistry curriculum of Alberta were developed which included links from the core materials to special issues in science technology and society. This study took six grade eleven students two teachers, two researchers, a representative of the environmental alliance of Alberta and the resources of the internet. A problem based learning approach was used and students had to answer the question 'What do the citizens of Calgary need to know about the safe transportation of chlorine through the city?'. The study revealed difficulties of using current web tools for problem based learning and argues for a specific architecture to support this style of learning for a future design.

Introduction

Learning in the classroom has and will continue to become more the responsibility of the learner. The distributed nature of electronic materials available from the internet creates a challenge especially for unpractised learners to manage and make sense of. At another extreme of instructional design in practice, author—paced tutorials do not support the kinds of explorations which are arguably more relevant to social and environmental issues. This study is motivated by a belief that socio—scientific literacy must be grounded on well understood core scientific knowledge. A measure of socio—scientific literacy might be the extent to which a reader can make well reasoned reactions to issues which require a scientific understanding when reported for example by the local media. The study is also motivated by the idea that such issues grounded in the experiences of all of us can motivate learning of the core elements in a science curriculum at the same time. Problem based learning (Duffy & Jonnassen, 1992) seems a likely solution to the challenge of a highly distributed and un—moderated resource base. Some evidence suggests that high levels of intellectual maturity and metacognitive abilities are required by students to benefit from problem based learning (Gallagher, 1992) however for those students who have not yet developed such skills some scaffolding devices may be necessary. The central role of this study is to test and provide design guidelines for multimedia software which was initially designed to be delivered by compact disk but which will in a new incarnation take account of related materials available from the internet and may itself become distributed. This study actively engages eleventh grade students in the solution of a problem designed to provide a motivating and challenging task and thereby to accomplish goals in the Alberta education curriculum. Sometimes the value of problem—based or enquiry methods tend to look at the development of skills in areas other than the discipline being taught such as critical thinking skills (Duffy & Jonnassen, 1992). This study assumes that those skills do improve through adoption of such approaches however the experiment is focused on the goals of science technology and society and the connections to the formal chemistry materials.

The study shows that using web based materials combined with the various search mechanisms proved an enormous overhead for students. The process of solving the problem was difficult as was the change to a facilitative orientation by the supporting instructor. Recommendations are made which should help alleviate the difficulties of problem based learning, to relatively seamlessly integrate socio—scientific literacy goals with formal chemistry, and, to make the interface do some of the facilitative work for the instructor. These recommendations are based on providing the inherent guidance of a fixed set of formal schema linking rhetorical and socio—scientific structures within an instructional design framework. This kind of system will enable generalisable problem solving in a constrained environment and provide the necessary systematicity to later add agent support. It will ease the process of writing courses for the author and make exploring chemistry and the links with its social implications less of an overhead for the student.

Another approach to evaluation.

This study represents a novel and challenging approach to evaluation in a continuously developing suite of evaluation processes and instrument development (Ross & Morrison, 1992; Dobson, 1994; Dobson & McCracken, 1997). In this case we are concerned with objectives based on: a) assisting the continued development of a software product, b) assessing learned outcomes in an area of formal chemistry, c) assessing development of skills related to socio—scientific literacy, and, d) evaluating the use of a problem based learning process as catalyst to all the above.

This study proved interesting in many respects including the development of facilitation skills by the tutor, development of problem based learning skills in the students and in the reactions learners and students had to the multimedia materials. Rhetorical structures of standard argument such as justification and evidence finding are bolstered by systematic approaches such as cost—benefit analysis, risk—calculation and reduction. Information processing at many levels is required in the apprehension of socio—literate skills. Even before the difficult process of assembling an argument or a problem solution simple acts of information sorting, pruning, discarding, prioritisation have to be carefully undergone. In the formulation of a final product a well reasoned response to an issue of science technology and society must be coherent, non—contradictory and generally sound in at least some informal way. All these skills are known to be difficult in well constrained domains such as physics (Simon, 1992; Van Lehn, 1991), and in less formal domains the problem may be more intransigent since argument is embedded in natural language. The science technology and society curriculum exists in the realm of informal social discourse but provides scope for the use of scientific and well defined justification for a discourse position.

Students of the level used in this study cannot be assumed to have developed the metacognitive skills required by researchers in monitoring their own learning (O'Malley, 1990). Problem solving is done differently by those who are practised at the skill of general problem solving (Chi & Glaser, 1985) than those who have not previously been successful. With such difficulty in both the process of self monitored learning and in problem solving for novices it might seem strange that a problem based approach to learning is considered a worthy constructivist model for the classroom. However inherent in the ambitions of constructivism generally is the added goal of a separate learning objective. Beyond learning the chemistry material a constructivist approach also aspires to students improving general metacognitive skills. The result of such a change in the goals of a curriculum alters the way in which learning interactions may be reasonably evaluated. No longer may we test students in the domain before a learning interaction then after and see the difference as equivalent to the only learning gains. It is often said that changes in the student's ability to learn the material under their own control should also be considered in an evaluation. Problem solving because of a clear sense for the solver of the end goal and because states of the problem solving process can be measured against the final solution can give the learner a very clear sense of progress and provide the information a learner needs to monitor their own successes.

This approach to evaluation castes distributed multimedia materials in the best light possible by creating an interaction style most likely to promote learning outcomes. The evaluation hi—lights difficulties with implementing problem based learning both for the student and the instructor. The approach is demanding of all parties involved which is more of a reflection on the technology we have so far been able to develop than on developmental problems of students.

A problem based study

The study used six eleventh grade students from a secondary school chemistry class who came to the offices of the Alberta Research Council in Calgary Alberta. Problem based learning as it has come to be thought of in current teaching organisations almost exclusively assumes a group project based practice. This study does not argue with that assumption although the chief value of the group approach for us was to provide externalisation of the problem solving processes to yield usable data to answer the evaluation questions.

Prior to the study each of the students had been introduced to the software program Chemistry—20 and had looked at material relevant to the problem to be solved. This gave the students experience at interacting with the interface which Chemistry—20 uses. Access to materials used in the study was moderated to help track what was used and to provide a range of interaction. Materials included: a) all documents available by internet, b) search engines plus support in how to use them, c) film footage of a train spillage, d) newspaper clips of similar disasters, and, e) a collection of pre—selected text books. As well as the six students in the room the study was supported and at times observed by: a) the class teacher, b) one of the researchers (collecting video data), c) the

BEST COPY AVAILABLE

software development director, d) the facilitator, and, e) a local environmental and chemical industry expert. These individuals had well defined roles for the experiment since the tenets of a problem based approach are quite clear and the roles which most of these individuals are used to playing are quite different. Teachers for example are more used to teaching than to facilitating and this number of supporting individuals would be very unusual in a normal classroom using a problem based approach. We recognised particular interests of the industry representative and moderated student's access to him by locating him in a separated office. The facilitator had little previous experience in facilitation although had conducted project work with his class in similar issues using a range of rhetorical support including cost—benefit analysis. The facilitator had reviewed materials outlining good practice as a facilitator the central tenets of which adapted from (Duffy, 1994) are worth reproducing here:

1) monitor phases of problem solving ensuring the proper sequence of phases and that proper attention is given to each phase;
2) probe students knowledge deeply;
3) involve all students in the group process;
4) make educational diagnosis by attending to problems in reasoning and understanding and in finding information;
5) probe a student in an area where you think he is having difficulty;
6) ask the student to reflect on his understanding;
7) modulate the flow of the process by making sure things don't progress too slowly or too quickly;
8) manage interpersonal dynamics, once they get to know one another group dynamics can soon break down and hostilities arise;
9) let students notice a problem if possible and help them deal with it and call for resolution as an out of class activity;
10) play a metacognitive role: refraining from giving information, from evaluating responses or input, and, by actively providing questions that challenge the student as often when right as when wrong, and finally,
11) wean oneself from the situation and support the students when they begin taking on the role you are playing and hence can function as independent learners.

The director of software development and co-ordinator for the study introduced students to other participants and held a short debriefing after the study was complete. The class teacher's role was to provide affective support and specific chemistry guidance should things go badly. The researcher's role was in data collection. The students role was to solve a problem and we had designed this problem so as to provide a good chance of solution and of making the connection between the formal chemistry and the socio—scientific issues which surround it. The problem eventually settled on was: "What do the citizens of Calgary need to know about the risk to the environment and society's safety as a result of a train derailment involving the chemical Chlorine?" The student's task was to produce a 'flyer' that answered the problem and communicated their findings to the citizens of Calgary. This flyer would later be distributed with a copy of the local daily newspaper to the homes of many thousands of people. Video data was collected throughout the day with a video camera located in the home room and notes collected by the principle observer both from first hand observation and by group interview.

General Observations

The facilitation role was not well understood to begin with and although the teacher charged with this role was supportive he spent a lot of time not engaged in solving the problem with the students. After direction he became more actively involved in the process until at the end of the day his report back to the debriefing group showed just how much he had learned about problem solving in learning and the role he had developed. This result is very encouraging. With relatively little preparation over the course of just one single day a teacher used to an expertise delivery model developed substantial understanding and practice.

We were surprised to find that the most productive interaction with the available resources came from the experts in the study. The resources that were used most in the study were those provided or directed to by the environment and industry experts. The most inefficient means of information retrieval which took place was time spent accessing web pages through search mechanisms.

Socio—scientific issues are very real issues with real stake—holders and real consequences for the society involved. The Alberta program of studies for Chemistry—20 (Alberta Education, 1994) takes this seriously and states the importance of "...the central role of experimental evidence in the accumulation of knowledge and the ways in which proposed theories may be supported modified or refuted" (p.11), and later, "the student should be capable of explaining the role of concentration in risk—benefit analysis and the significance of biological magnification in increasing the concentration of substances within ecosystems in terms of protecting the environment from harm to ensure the quality of life for future generations" (p. 13). The internet provides a place for all stake—holders and interested parties to make their case available to a public audience. The visibility of that material is increased by: a) features of search engines and any awareness an author has of how such tools work, and, b) the extent to which the material draws attention from a public and is informally cited to peers. The importance, value or truth of the material as would traditionally be judged by panels of referees, lecturers and other experts is lessened in the determination of this visibility. This fact may well be a good thing leading to a democratisation of the knowledge building community.

This study provided a real example of this process involving stake—holders from government, industry and education and access to materials written by people with the whole range of possible positions. The discomfort involved in presenting sensitive views from professionals representing particular stake—holdings was evident. The influence of the groups in this study either perceived or actually present was at least coincident with a moderation in the scope of the project. This moderating effect was achieved by arguing for rhetorical structures which suited the stake—holders involved. In the development of a problem for students to solve which is a pivotal point in creating a good experience for learners (Duffy & Savery, 1994) the focus of the study changed from the initial suggestion of: a) a risk—benefit analysis of the production and transportation of chlorine through the city of Calgary to, b) a study in risk—minimisation in chlorine transportation, to the eventual study, c) which essentially demanded an information leaflet for 'What to do in case of chlorine spill' — the kind of information often found in the front of the public telephone directory. Risk minimisation is an objective appropriate to an industrial perspective but misses the remaining rhetorical structure of the cost—benefit analysis by almost assuming that the risk is worth taking whilst at the same time trying to minimise it. The eventual study based on the flyer left little room for discussion of the issues involved placing the authority for making socio—literate comment in the hands of experts. We had expected that students would think it important to make the facts available to the citizens of Calgary and allow them to decide if the risks involved were tolerable (we had no doubt that they were). In this way factors such as but not restricted to: a) the probability of train crashes and leakages, b) the extent of spread of Chlorine gases, and, c) the impact of contact with gas on the human respiratory system, could all be assessed in context and evaluated for acceptability by the public of Calgary. Bringing high—school students to the point of making the links between science and society as required by the Alberta Curriculum is a difficult but essential objective and should not be treated lightly. One of the outcomes of this study was that bringing in stake—holders at an early stage may lead to conflict not just in stake—holder point of view which would add to the interaction but also in the rhetorical structures appropriate to the task.

Data capture

The study was relatively complex involving at least ten people over a period of some five hours. Work spaces were created in different locations, information was available from different sources, conversations went on both in small and larger groups. A problem solving meeting room was established where most of the work and communication was to occur. We made all the usual supports available including white boards, flip charts and over—head projectors. It was hoped that much of the communication would go on in this home room and we could catch all this data. Unfortunately the study suffered sometimes overwhelming difficulties in the collection of data indicating the extreme caution required in setting up such loosely conceived ethnomethodological studies. These problems are regarded as useful results in themselves and will contribute to the generation of a data capture environment at the University of Calgary for studies of this kind in the future.

Implications for Chemistry—20 software

Learning level 20 Chemistry involves the apprehension and integration of complex technical material with connections to difficult socio—economic issues. These issues can help to ground the learner with situations they are already aware of and to help him find a motivation to learn the formal chemistry required. These materials also help locate the impact the real work of science in the community has on human life and the environment. When these objectives are combined with the need for the student to be solving an authentic problem learning

BEST COPY AVAILABLE

can be very exiting. The task of this study is to provide guidelines for software development that will allow elegant movement within the material including both the core materials and the socio—scientific issues. The problem is exacerbated by the current trend towards ubiquitous learning where very many people including teachers, politicians, industrialists and pressure groups are keen and able to provide their perspective on socio—scientific issues through the feral medium of the internet. Many of these groups do not agree on conclusions to such issues and often differ in rhetorical standards. Any process of problem solving takes place in the context of multiple forms and in each form at multiple levels of complexity, detail, accuracy, and abstraction (De Jong, Dobson, Sime, Spada, & Van der Marke, in press). The challenge is to make information available so that learners may solve the problem at a level of abstraction enabling a good chance of transfer of both the problem solving skills and the domain material to new and more difficult contexts. Studies in the development of early logic learning (Van der Pal, 1995) show that there must be a balance between the situated nature of the environment and the formal representation. In the science technology and society curriculum the conceptual tools and representations available to the learner are manifold. The formality of the material is high in the chemistry part but low in the social implications part. This range of formality is only one dimension of difficulty in representing the material for exploration by a problem solving learner.

Given the complexity of problem based approaches we propose a simplifying technology in the form of a generic set of schema based on analysis of learner requirements and teaching objectives. Material will be integrated and navigation initially user defined and later automated making use of learner characteristics and progress at the domain. The web based environment brings the opportunity of a flexible formalism in SGML to bring together conventions of rhetorical structures (Toulmin, 1958) with the formalisms of risk benefit to the level of chemical reactions themselves. Once these schema are created the process of course authoring becomes the process of identification of material for particular frames in such a representational scheme. Predictable patterns of representation from the environment remove the overhead to students of learning new structures.

One way to achieve this kind of interactivity would be to code each small stage of a reasoning process into a specially created SGML tag system something like BELVEDERE (Lesgold, 1995). A cgi script acts as an interface to a knowledge base of facts and relations within a domain. The knowledge base is able to answer queries and give explanations for answers to those queries or to provide a sequence of argumentation events presented as a kind of narrative without the user providing a specific query. This is a web based intelligent tutoring system except that instead of using complex authoring environments or developing the tool from first principles the SGML environment provides a ready made schema development environment for creating the knowledge base. A cgi script would be developed acting as the expert tutor and a student model would be developed over time by the system. This is a high—end solution which would require considerable months of development and modelling investment. A solution such as this would compare well with other intelligent internet tools (Brusilovsky, 1995). An engine for course delivery such as this would be complex for the average courseware author although with better authoring its prospects might be improved.

A more realistic recommendation for a system would still likely show gains in learning and at the least an improved speed in problem solving for the problem based learner. This solution would be simple to implement and yet is not known to exist. The goal is to move as much of the facilitation role from the human facilitator to the interface design by maximising the efficiency of conventions used and by constraining the scope of communication to primitives relevant to the user's task. Of all the schema which might be brought to bear here the most reasonable would be based around the rhetorical structures of socio—literate discourse. We therefore choose the rule based informal reasoning schema of Toulmin (1958) as the central device. The primary components of this schema are based — for the purposes of an HTML implementation — on typed links relating to Toulmin's work.

Tags will be created for a first implementation of such a schema and would include: a) claims, b) data, c) warrants, e) rebuttal, and, f) backing. In the original Toulmin structure modality is an operator over claims, backings, rebuttals and warrants - but may not be necessary in a first implementation. These tags will be assembled in the following ways: a) claims - whose truth we seek to establish by argument, b) data - that we appeal to as the grounds for the claim, c) warrants - which provide the rules of inference that connect the data with the claim. These degrees of support will be indicated in the second prototype by the use of: a) a modal qualifier such as necessarily or possibly — there may also be exceptional conditions which prevent the claim from being established and these are indicated by the rebuttal which contains circumstances acknowledged as requiring the authority of the warrant to be put aside. Warrants also require some justification which is the role of the backing tag. The actual implementation of such typed links in web based material would involve the creation of SGML tags to show each of these features. For the user they would be presented with individual identification of material which fits into their own construction of the argument relating to the issue and problem which is being solved. This effectively introduces a cognitive support tool based on the specific use of the web materials for problem solving. The tags will be used in two different ways by a problem solver. Firstly this form of representation helps him to understand material which is already created by others and promotes a critical reading of such argument through the explicit nature of elements in the text. Secondly such a tool allows a problem solver cognitive support in the construction of their own solution to a problem. To summarise recommendations for the development of courseware for supporting problem based learning in both formal and socio—literate parts of the curriculum the following approach would be taken:

1) move implementation to a web based environment based on HTML and SGML;
2) develop a system based around Toulmin's argumentation schemas in three independent stages where tags appear to the user as differently coloured hi—lighting indicating typed links to material which contains: data, claims, warrants, rebuttals and backing;
3) a second implementation would use the modal quantifier added to the claim, backing, rebuttal and warrant tags from which a diagram of the argument structure should be automatically drawn;
4) discussion should be facilitated through the medium of an internet conferencing system where an on—line facilitator should be available;
5) a study would be conducted with different support techniques aiming at reducing human facilitation by providing on—line cognitive support;

Although the description here is based on a web delivery there is no reason why this framework cannot be used to deliver material in stand alone format the only requirement is that at the lowest level of representation the same set of SGML, HTML conventions must be used.

Conclusions

As researchers used to the high personal overhead of focusing on specific research questions and monitoring our successes over time we may forget how easy it is to become distracted by questions equally as interesting as our original goals. This study represents a close to ecologically valid example of eleventh grade chemistry students from the Alberta educational system solving an authentic problem in the socio—scientific area directly in line with the local curriculum. Students were asked to use a range of resources varying in all aspects of mediation, retrieval ease, relevance, and accuracy. This kind of learning environment may be one of the most beneficial of the various forms of constructivist motivated experiences. Certainly the level of engagement in the learning task reflected the predicted high sense of task ownership motivation and goal orientation that the problem based learning delivery style advertises. There is evidence from the dialogues that the goal orientation supported the direction of the learner keeping them on track and therefore avoiding becoming lost in the enormous range of material available to them and therefore providing for a low requirement for tutor guidance. These positive results are moderated by findings that students had significant problems in adhering to the requirements of good problem solving particularly in decision making, pruning of superfluous information, communication between task groups, timing and planning. The study indicates that good facilitation skills appear simple and intuitive but take great effort and practice. Our trainee facilitator built up a good grounding in these skills through the practice of the day but this represented a huge effort on his account. There would seem to be a need as indicated by all of the senior project team in the final debriefing for instruction in problem based learning and or problem solving in general.

The main result of this study from the point of view of evaluation of the materials which were available to the students and the implications for electronic delivery of the Chemistry—20 curriculum will determine the most significant implications for further development. The most effective means of high quality data retrieval for problem solving came from an on—site expert who knew from a certain amount of prior warning exactly where to put his hands on material which could be used by the student. Unfortunately we are not in a position to replicate this kind of retrieval mechanism and so this result represents a future goal. The mechanisms available especially the internet search engines caused extreme difficulty to the students both because of the enormous amount of material on the web (a problem that will only get worse) and because the process of search was alien. The striking contrast in the time spent in accessing material from each source compared with actual source of content in the intermediary product exemplifies this finding. Several recommendations are made for development of the courseware which will serve both the loosely defined nature of representation is science technology and society issues as well as the well-defined nature of formal chemistry itself. These recommendations should build a seamless link between those two parts of the chemistry curriculum helping to motivate the student through the connection with the formal to the environmental and help them to more properly understand the rhetorical structure of informal argument and how it may be supported by experimental evidence and scientific understanding.

HYPEREXP: A Generic Hypermermedia and Knowledge Based interface to Teach Decision Making.

Aude Dufresne, Ph.D., University of Montreal
C.P. 6128 Succ Centre-Ville, Montreal, QC, CANADA
dufresne@iro.umontreal.ca

The teaching of decision making is an interesting domain for Intelligent Tutorial System, since the systems developed can serve first for training but eventually as task support environments. The HYPEREXP environment was designed to help the visualization and understanding of decision rules in order to teach decision making. It was designed to be a generic environment, where the application and knowledge are completely separate, partly so the later could easily be adjusted. The system uses a graphical representation of sequential dependencies among knowledge elements organized in contexts. It offers passive and active help, presenting contextual and hierarchical explanations on the on going process. The knowledge and the hypermedia structure of explanations are described in external databases, which are easily modified by non-expert and which can be displayed for explanation of decisions.

Context of the research

Knowledge representation and understanding

The problem of knowledge representation and understanding as been investigated not only in the context of learning, but as a first step in the domain of knowledge acquisition and validation. Various formalisms have been proposed to communicate with experts on their strategies of decision. First, rules are modular, easy to understand and have long been used as an efficient way to describe strategies. Though if each rule is easy to understand in isolation, their interactions become very complex, when they are all combined in execution. Clancey (1983, 1985) working on MYCIN pointed out that the rules have to be organized in a hierarchical fashion following general heuristics of decision in order to be easily explained and learned.

If a general level of abstraction is important to apprehend the global heuristic, various formalisms have proved to be more efficient to describe more detailed aspects of the decision. For example, tables are useful to facilitate a more analytic and systematic examination of decision rules especially in complex domains (Yazici, Muthuswamy, & Vila, 1994). Boose, et al.(1988) have used tables to bring experts together in establishing relative weight to relations among concepts.

Finally, simplified graphic representation of dependencies among knowledge elements have proved to be very useful to simplify the understanding of strategies (Holtzman, 1989). These graphics serve as a synthetic representation of the decision, they help the understanding and reminding of contextual information during the process of decision.

These various representations complete each other in bringing both a general and a detailed understanding of the strategy. The present project following our previous research with the ALADIN knowledge acquisition system (Dufresne, Muzard, Legault, & Dufour, 1992), tries to integrate graphics, tables and rules' representations of decision to facilitate the understanding of strategies.

Interfaces to facilitate learning for complex tasks

Research on learning environments to facilitate learning of complex tasks like programming or decision making recommends to leave some initiative to the learner so he can really develop a representation of the problem and also pace the exploration to his understanding. According to Jonassen (1993), it should be a "generative environment where the user has to do more processing, enabling him to think and learn on a higher plane". More passive learning leads to a "reconstruction learning" that does not favor transfer of knowledge, and seems even less adapted for the learning of heuristics.

On the opposite we found that users preferred more control from the system (Dufresne, 1992) they wanted to be guided, when they are learning complex procedures. While learning database operation, learners preferred a linear environment to a more flexible one. In fact graphical cues in the interface and feedback on their progression was found to be sufficient to guide them and insure that they would complete the exploration.

A more flexible hypermedia environment to access knowledge and a more declarative approach to teaching, seems to impose a higher cognitive load that is stressful to the user. The difficulties to explore the interface and to keep track of the navigation interact negatively with the learning process. Kay, & Black (1990) describe steps in the learning of procedures going from examples, to alternatives and more complex plans. These suggest that a certain progression in the description of the strategy is necessary and that the level of control and help should vary as the user progress in his learning.

The problem of teaching complex heuristics has some differences with the teaching of procedures.

We think that both functional and declarative approaches should be reconciled, and offered to the user in a richer adjustable environment. The user should be given the opportunity to have a flexible and guided introduction to the strategy. As a first step he may be introduced to the domain following a structured scenario, and the learning of simple relations. These would then make it easier to later proceed to the learning of more complex heuristic declarations and relations stating alternatives or exceptions.

Also, graphic representation of the association between elements of knowledge can help users build their representation of the problem (Heeren, & Collis, 1992). As Zhang and Christopher (1987, in Yazici, et al., 1994) propose "mental pictures with context instructions improves performance... the possible reason is that the picture display helped subjects to store the relationships between the system variables in working memory, thus functioning as a memory aid.". So following Kay's, & al. (1990) approach we propose to use both a graphical overview of the decision and to give examples to facilitate the building of a functional and analogical model of the domain (Sebrechts, Marsh, & Furstenburg, 1990).

These graphical overviews should be organized according to the contextual structure of plans, as they unfold to test various hypotheses in succession as the decision progress. If plans are an important part of the understanding of novices, more complex schemas are developed by experts as they gain experience. The possibility to explore difficult cases or enter new one should later help the learners to test their plans and to develop experience and efficiency in their understanding.

Hypermedia interface to facilitate learning

Studies on hypermedia design suggest different tools to support the navigation process that can be very useful in the context of learning. Both global and local maps of hypermedia information are important to support orientation and remembering of the structure of information. These maps should be developed to highlight the structure of the information, following various ergonomic principles: semantic grouping, internal and external coherence. If a global overview of the relations of the domain is important, we found that contextual cueing is also important to direct attention in complex environments and to support the learning process (Dufresne, et al. 1990,1991; De La Passardière & Dufresne, 1992). Constraints can be added to navigation maps, to dynamically highlight importance or scheduling of the more relevant elements at a specific moment. Elkerton, & Williges (1989) also suggest to adapt the interface to the user progression, using both active and passive help, giving more feedback to the user. We found that graphical properties of the elements in the interface could serve as non intrusive feedback to guide the progression of the user telling him what he has already done, how he is doing and what he should do next. Historic feedback (footprints, timelines) not only guides the user in his navigation, it encourages him to complete his exploration.

Finally we found that if users prefer to have the information organized for them, they needed diversity in the type of learning material. Access to explanations, examples, exercises and tests on the same material was important to bring them to an active learning process, especially considering differences in initial knowledge, and in cognitive style (some would rather risk a test, other preferred to be guided , some would peek at examples before they start reading definitions.

From knowledge representations to learning systems

Explanation of decisions was the first step to transform knowledge base systems into teaching systems. HOW was a decision taken? or WHY is an hypothesis pursued ? were used to described the rules used for decision making. As Clancey (1983) have shown explanation of specific rules is insufficient to help the user develop his understanding, because rules are too modular, technical and appear without their general context. Heuristic should be explained at a more general level.

Guidon-Watch was developed to integrate explanations in a contextual and time-dependent fashion, but the unfolding of hypothesis and decisions tend to make a very complex and textual interface, which was very difficult to read and follow for the learner. The interface should be more adaptive to the user needs.

Bergeron (1994) experimented a system to diffuse medical knowledge, where users were left to choose the level of explanations they wanted; they used filters to get expanded acronyms, definitions, normal values, level of details, etc. Normal values were the more frequently used type of filter.

As for Hypermedia systems developed to teach decision making in medical science, they may be grossly characterized by two types: cases based and encyclopedic knowledge. In some area a limited number of schemas is sufficient to help the learner grasp the basics of decision making. In other cases, the decisions are based on perceptual discrimination of properties; in those area a well-organized database of examples can be useful to serve as a reference and teaching tool. In most area of decision, both approaches appear to be insufficient to foster a general understanding of the decision process and an eventual transfer to similar or more complex cases.

Finally the integration of hypermedia and simulation environment poses the problem of adapting and actively defining contextual structures of hypermedia explanations, depending on what is the active context and the user needs at one point in the decision process. It also poses the problem of allowing more flexibility and control to the user in a knowledge base environment.

Description of the system

Statement of the problem

The objectives of the research were to develop and investigate an efficient interface to teach decision making. Studies in fact are contradictory, they point at the necessity to control and support the user through scenarios, but also to bring him to be active and reflect on general meta-strategies. In fact the level of control of the system have to vary or adapt itself to suit the user cognitive style, his level of understanding, and his developing expertise. This problem of mixed control poses the problem of coherence and transparency of the interface. How can the interface be transparent enough, so the system can help the user without surprise or interruption? How can it be simple enough, so the user can fetch additional help when needed?

If the balance of control between the user and the learning system should be varied, so does the content of explanations. It should be possible for the user to choose the types and level of explanations, he wishes to have automatically (active help), and which one he could get when needed (passive help). Those explanations should be offered depending on the task and learning context and they should be organized hierarchically so the user can have general information and then be left free to explore in more details.

A visualization of the planning structure and also temporal and schematic cues appear to be important ways to support the user in his understanding of the evolving decision. Since decisions often have a perceptual and qualitative dimension, graphics, images, audio and videos can also be helpful to develop a more analogical understanding of the phenomena.

Simple, easy to update and a front end for research

Before describing the HYPEREXP system, it is important to consider the constraints that were considered in its design. First, in designing the interface, it was important to avoid the double learning problem, which meant that the interface had to be simple enough so the learner could concentrate on understanding the content not on his manipulation of the system. The second constraint was that the system had to be easy to update and to prototype. Since knowledge elicitation is a difficult and never ended task, it was important to define an environment where the knowledge base and the explanations could easily be updated, by domain experts.

Finally the purpose of the system was partly to experiment functionalities and versions of the interface, so it was important to include in the system, functionalities to keep traces of the user manipulation and also his comments on the content and on the system.

Design principles for the interface

Considering the complexity of the content to be learned, it was important that the interface be both controlling and guiding the user progression, while leaving him some flexibility for exploration. The interface had to offer a simplified view but transparent account of what was guiding the decision process.

The design principles for the interface were to offer:

- flexible and contextual access to data-entry, rules and explanations
- hierarchical levels of explanations, both active and passive, starting from information on the meta-strategies and planning and going to detailed account of the rules and objects of knowledge.
- different representations of the elements of the decision process using schemas, graphical animations, tables and rule representations and multimedia illustrations of phenomena for symptoms identification and explanations

A generic system developed using external tools

The system was defined independently of the knowledge and explanations, in environments where it was easy for domain experts to organize and consult them. We used spreadsheets (Excel) to represent the rules and database (FileMaker) for objects and explanations. The HYPEREXP shell was developed in Hypercard that made it easy to prototype the interface, to develop multimedia functionalities and to link to external applications.

Representation of the decision knowledge

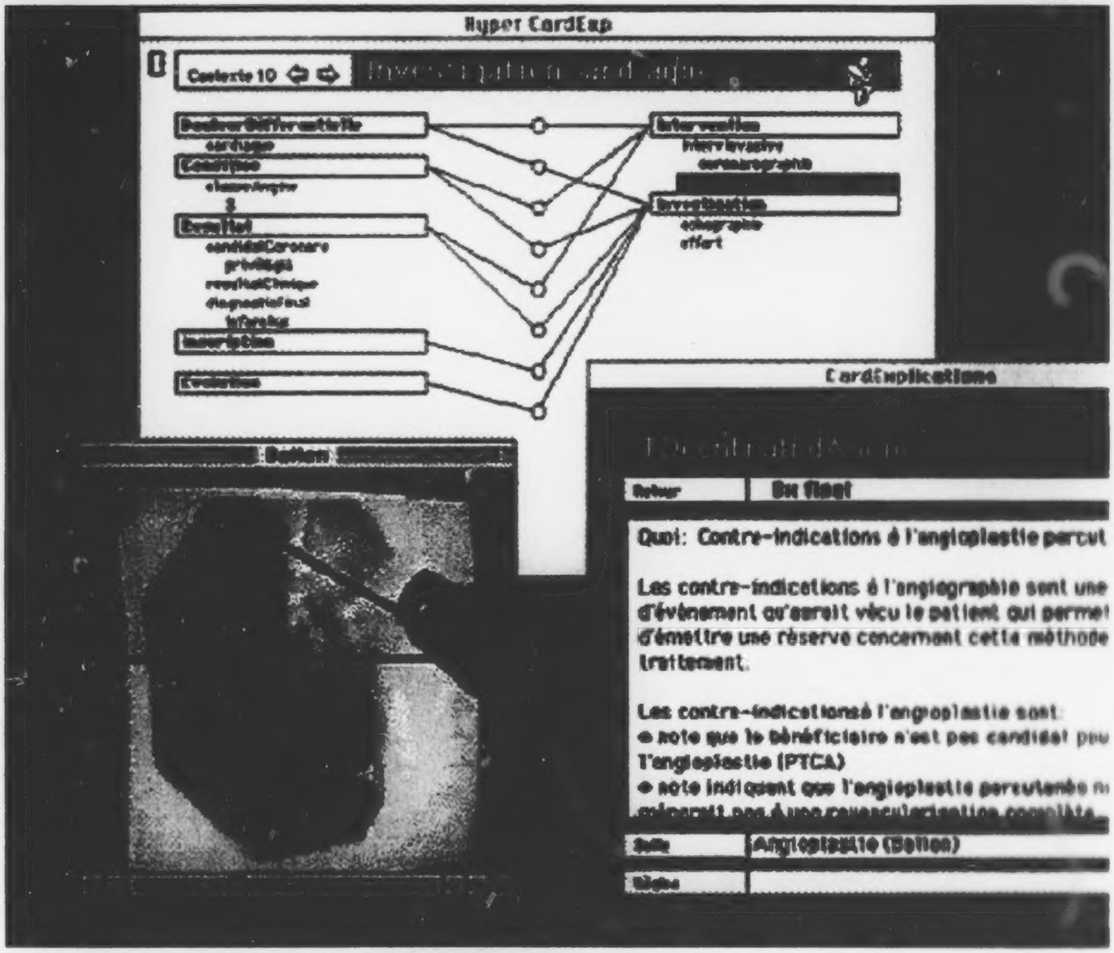
The strategies are presented as a structure of different contexts, where various elements and their relations are presented to the learner. This schematic representation makes it easier for him to understand and remember the global structure of plans (see also Yazici, et al., 1994; and Heeren, et al., 1992, for the importance of schemas).

Finally contextual structures of explanations were described and organized hierarchically from general to specific, answering question like What is this parameter ? Why should I know it ? and How can I decide its value? For each query, a general answer is given, from which the user can pursue on more detailed or related subjects. Active tutorial interventions can be described in the Explanation and Knowledge databases. Systematic explanations are scheduled to appear as decisions are made or as the context changes: Why pursues this hypothesis now? And How should you plan and decide in this context?

Once knowledge is described, it can be imported, compiled and tested in the HYPEREXP inference engine and interface. The graphical interface for the different contexts of decision are inferred from the compiled description of knowledge elements. It is organized hierarchically in classes, properties and values that can be explored and manipulated by the user.

Fig. 1 - Example of interaction with the CARDEXP system explaining a cardiac intervention.

The system



Quoi: Contre-indications à l'angioplastie percut

Les contre-indications à l'angiographie sont une
d'événement qu'aurait vécu le patient qui permet

traitement.

Les contre-indicationsà l'angioplastie sont:
• note que le bénéficiaire n'est pas candidat pou
l'angioplastie (PTCA)
• note indiquant que l'angioplastie percutanée n

Angioplastie (Ballon)

Figure 1 presents an example of interaction with the interface.

The graph present how some parameters influence the decision on a cardiac intervention. It is dynamically modified as the user enter values. He can adjust more than one parameter at a time to see how they interact on the decision. The graph represent the hierarchy of the classes, parameters and values. It is partly elastic, since each class can be stretched to view or closed. (These are similar to local and global maps in hypermedia.) Each parameter can also be opened to change its values. As the user enter the values, he can visualize the effect of these added knowledge and ask question on it. His attention can be guided both graphically or through active hypermedia explanations. The system can be used to explore typical cases or to enter new ones. The user can adjust the level of feedback he receives automatically.

Discussion and Prospective

The HYPEREXP system proposes an environment to support the learning of complex decision making. The system combines aspects of strategic explanations like in GUIDON-Watch, a graphical representation of the decision process that has proved to be helpful to support understanding and remembering of knowledge and the power and

BEST COPY AVAILABLE

flexibility of hypermedia explanations.

As a first step we wanted to make the system adjustable by the user himself and to investigate how he choose and evaluate the elements of the system, especially depending on his initial level of expertise of the domain. We will eventually develop adaptive functions in the interface, so the level of feedback and explanation is automatically adjusted to the user navigation and anticipated needs. The explanations actively presented at the beginning of the session or cases chosen for demonstration could be replaced by others as the user demonstrates his understanding.

The system is interesting because it offers a generic structure to develop knowledge base multimedia environments to teach decision making. We are currently using it in two areas of decision making: for the diagnosis and treatment in cardiology (CARDEXP) and for repair and restoration (REX).

Also, since the knowledge and explanations are defined independently, they are easy to update, which accelerate the prototyping and adjustment of the system. This could eventually make possible the sharing of knowledge using the system, the users could add comments, new cases or additional references using specific forms in the system. These could be controlled and added to the knowledge base.

Abstract: There is a great deal of courseware being developed for delivery on the World Wide Web today using standard Web browsers. While Web browsers do many things extremely well, they are not specifically designed to provide direct instruction as are systems such as Authorware Professional ®. Rather than try to force a Web browser to become an instructional system, we have added network capabilities to Authorware Professional to allow it to communicate over the Internet to load and update Authorware Professional modules, keep track of student restart data, student performance data and user license data. One of the side effects of using Authorwaree Professional rather than a web browser is that the source code is well protected since the user accesses object code only.

Introduction

In the past, Computer Based Instruction (CBI) courses generally were delivered using main frame computers. systems such as the IBM 1500 and Control Data Corporation's original PLATO (Programmed Logic for Automated Teaching Operations) were capable of delivering course materials simultaneously to a number of students. These systems were also able to maintain an extensive centralized data base that recorded individual student activities and progress. With the courseware being delivered from a centralized location it was a relatively easy matter for the instructor to make course content corrections or updates. This updated courseware was then immediately available to students. While very successful, these systems were limited because course materials could only be delivered to students who had access to terminals connected to the mainframe.

The advent of the microcomputer has made possible the independent delivery of CBI course materials at any number of locations. Course materials can be delivered to students on floppy disks or CDs, students only need access to a microcomputer capable of running the software. With the need to be connected to a mainframe computer eliminated, microcomputers provided an avenue for instructors to reach a wider audience. CBI courses can be delivered virtually anywhere in the world.

However, this method of delivery has its own drawbacks and limitations. Foremost is the static nature of this form of instruction. Once written and distributed it is an expensive and time consuming endeavor to redistribute course material when corrections and improvements are made. Also, the loss of a centralized database of student information (student answers, latency, study patterns) that could be used by course authors to improve instruction presents a second limitation.

This project uses the Internet and some specialized tools to combine the mobility and ubiquity of the microcomputer with the centralized database and ease of updating course materials previously only available with mainframe delivery. The project had three goals. One was a system that would allow a student to start a CBI course at one university, then move to a different computer or even a different country every day and continue the course at the precise point where it had been discontinued the previous session. The second was to make the newest updated version of the course available whenever a student started regardless of physical location. The third was to maintain a database of student information.

In short, as long as a student can connect to the Internet, that student has access to the latest version of the course and is able to continue were the previous lesson left off, regardless of physical location. As well, any course work done by the student is recorded and stored in a centralized location.

Problem

Project Goals

The intent of this project was to demonstrate an Internet-based file management system for microcomputer-based CBI courses. More specifically, the project was designed for use with courses authored using Authorware Professional ®, hereafter referred to as Authorware, in the Macintosh environment. The project's main focus aimed at developing a method of CBI course delivery and maintenance to remote locations using the Internet as a medium.

The project goals were to allow for the maintenance and updating of student records, regardless of student location; restart a student at the appropriate point in the course, regardless of the computer being used, or the students physical location; automate the updating of revised instructional modules; allow student to easily report errors/problems in course materials; and design and implement a license data-base.

Delimitations

The following delimitations were imposed to enhance project manageability. This project assumes the availability of a continuous Internet connection; the availability of unlimited storage space for user files and programs on the server and personal computer (PC); the initial Authorware course module is located on the individual student machine rather than a LAN server or similar delivery platform; and the Macintosh environment.

Quick Overview

Server

Hardware

This project was developed using an IBM RS/6000 *Server* using IBM's AIX (Advanced Interactive Executive) 3.2 operating system. It has since been ported to a Sun SPARC Station Server using the Solaris 2.5 operating system. The decision to use a UNIX based operating system was partly based on the need to develop the communication tools required to transfer information between the server and client user, tools best served by the UNIX environment.

The server operates as a stateless server (Dewire, 1993). That is to say, the server does not maintain information about the status of ongoing or previous interactions with clients. The server receives a message or request from the client, processes it, sends a return message and exits from the interaction. Each request is dealt with independently with only a single request being accepted from a given client at one time. The obvious advantage of using a stateless server is the reduced resources required for each client connection. The stateless server ideally suited project purposes where the information being transmitted at any given time can be viewed as an independent packet requiring a single response.

Another advantage of using a stateless server is that either the client or server can crash (unexpectedly fail or shut down) without causing difficulties for the other. In the event that the server crashes the client has only to repeat the request until the server responds. If the client crashes there is no degradation in the server's operation. More specifically, in the event of a server crash the student is able to continue with the lesson as if nothing has happened and seek a server response once the server is again operational.

To track student activity we have installed a system log file that records all server activity. This file is updated with each information request and includes the date and time, user ID and, the nature of the request

Command Language

The server commands are written in Perl (Practical Extraction and Report Language; Wall, Christinansen & Schwartz, 1992, 1996). This is a scripted language used for the manipulation of text, files, and processes and was chosen for its relative simplicity and platform independence. Our main concern was that client/server communication be as efficient and rapid as possible. This is an important concern if we want to provide client/server interaction that is as seamless as possible for the student.

The server commands are written using an "elsif" structure where the appropriate loop is initiated with the given command as the key. Owing to the stateless nature of the server, and the elsif structure, a given command string can only initiate a single process. Thus, repetitive commands require that the user repeat the request.

Commands are sent by the client using TCP/IP (Transmission Control Protocol / Internet Protocol). These commands are sent as a character string containing the server address, user ID, user password, and the command string.

At the conclusion of each command sequence, a character string is returned to the client indicating success or failure of the command. Successes are indicated with a simple returned text string "Succeeded." Failures are indicated with an explanation of why the given command failed. Depending on the nature of the failure, the user can make the necessary corrections and try again.

Client

As noted earlier, for the purpose of this project, client is any Macintosh computer capable of maintaining an Internet connection and running the Authorware courseware. Work on the project proceeded on the assumption that client was delimited to a continuous Internet connection to facilitate the transfer of information as seamlessly and unobtrusively as possible. Other than at the initial login the student should be unaware of any client/server communications.

The TCP/IP protocols available on the Internet make it possible to create an ubiquitous environment for our client users. In other words, the only limitation to client location is the availability of an Internet connection.

Communication Protocols

The communication link between client and server is maintained via the Internet. While the client requires a continuous connection to the Internet the connection to the server itself is only made when the client requests or sends information. The two protocols needed to access the system are TCP/IP and FTP. A third protocol, Telnet, is used by the system manager to administer and operate the server. These three protocols are part of what is known as the "Internet protocol suite" (Hedrick, 1987).

This project required use of some specialized tools that allow application of the above protocols. Specifically, AWQuery and AWFTP XCMDs (pronounced x-commands), were written for this project by an external consultant.

AWQuery

AWQuery establishes a TCP/IP connection with the server. Commands are sent from the client to the server in the form of a character string via this connection. The server parses the string, interprets and carries out the command, and sends a reply.

AWFTP

AWFTP is used to move larger files and programs using the Internet protocol FTP (File Transfer Protocol). This routine allows the provision of remote updating of revised modules as well as storage of student progress data.

TELNET

This is the third protocol used to access the system. There are no special routines or commands written for or used by this protocol. This is to be used solely by the *Manager* to work directly with the system files and functions not accessible through the user interface.

Client/Server Communication

The project design requires that all client/server communication be initiated by the client. The parent server computer was configured to allow communication to our independent server process through a designated socket or communication port. In other words, direct and continuous communication is available to the work space designated to this specific project.

When a command is sent to the main server computer, it is routed through the designated socket and received by the project server process. A child process is spawned leaving the parent waiting to respond to a request from another user. The child process carries out the command, sends a response, then shuts down. This enables the server to respond to a number of users simultaneously.

To allow different servers to be used for different courses and/or physical locations, part of each communication string sent from client to server contains the physical Internet address of the server.

File and Records Management

Four user groups are identified: student, lecturer, license holder and system manager. Each user group has different needs and requires separate access and interactive capabilities. The needs discussed below cover the basic requirements for each user level and are hierarchical in nature. That is, each higher level is granted the privileges of the preceding one.

Student

A student is any user accessing the system as a course learner. Few privileges are needed at this level other than the ability to access course materials, performance and personal records, and to check the license data-base. To accomplish these ends the user must be provided with a means to connect and log onto the system; access to updated modules; store and retrieve progress data; store and retrieve personal files; and send messages to course developers. In addition, the project design allows the transfer of files in a manner such that the user is unaware that client/server communications are occurring.

Login

The project design provides a means of allowing the student to successfully connect and log on to the system via a small Authorware program, which utilizes the AWQUERY XCMD, and allows each individual student to send and confirm his/her ID and password to access server resources. For security reasons, the command strings necessary to complete this task are hard coded into the software.

The only time an individual student must interact with the server is during login when the student is required to enter an ID and password. This information is then used in client/server interactions to access student specific files and records. Access to server resources is contingent upon the correct entry of a legitimate ID and password that is associated with a valid user license.

If the student does not enter a valid ID and password, or the user license the student is associated with has expired, a message is displayed that access to the server is denied along with a reason why. The student is, however, given the option of continuing with the course modules which exist on the client computer.

Once the student's ID and password have been verified, a request is sent to the server to determine if a record of the student's e-mail address exists in the server's records. If not, the student is asked to enter his/her e-mail address, if available. If the student does not enter an e-mail address, this request will appear on each subsequent login. E-mail addresses are used as a means of responding to student questions.

Module Selection

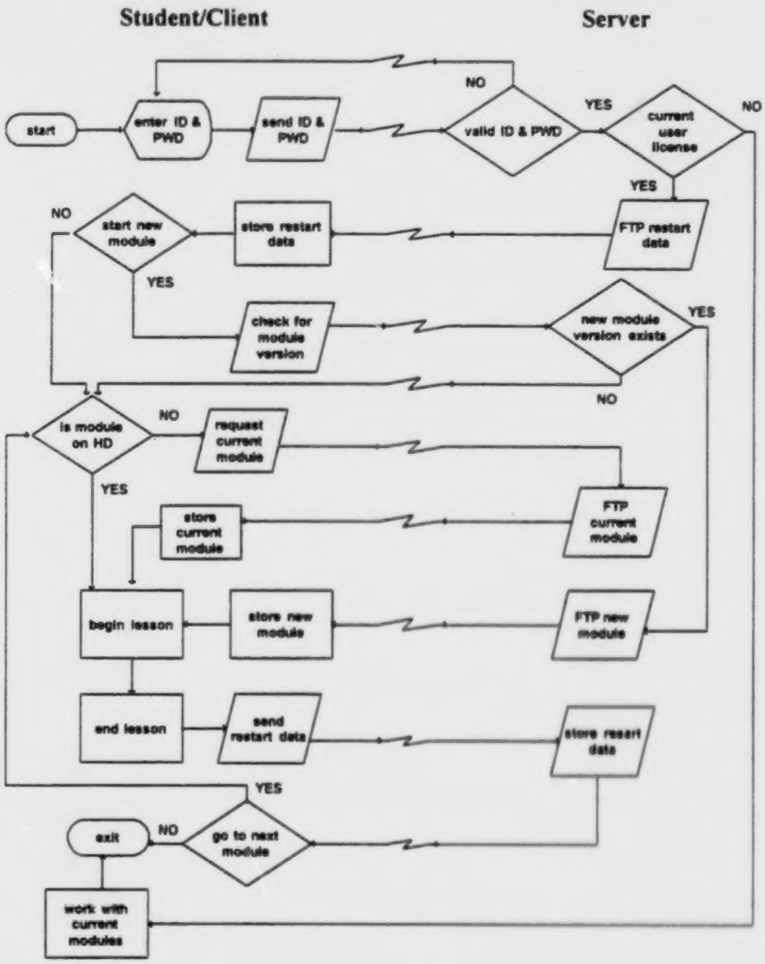
The majority of the work required to access updated modules and the retrieval and storage of program data is carried out by another Authorware program called the "router". Student restart data and new modules are transferred by the router using the AWFTP XCMD. The student interface was created by Jamie Higham

(University of Alberta Authorware Programmer) as part of a course called *Understanding Statistics*.

When the student selects a module the request is sent to the server to determine if this is the first time the student has started the module. If the student has previously started the module, the restart data is downloaded to a user folder. Before the student is allowed to continue, a check is done to confirm that the module exists on the student computer. If the module does not exist on the student computer it is downloaded. If the student is continuing with a previously started module the student begins at a "restart" point which is the exact location in the course where the student previously exited that module. It is possible for a student to have started a number of modules. A restart location for each module is stored as a separate file and only accessed when the student chooses to continue the given module.

If a module has not been started, a request is sent to the server asking for the version number of the most current module. This information is then used by the client to determine if this module is available on the hard drive. If the module exists, no further action is taken and the student continues with the lesson. If, however, the module available on the client hard drive is outdated, the updated version is downloaded via FTP to the courseware folder. Figure 2 is a simplified representation of the client/server interaction during a student session.

Student/Client/Server Communication



Student/Client

work with current modules

Figure-2: Client/Server Interaction

Message to Authors

Our experience and that of others (Alessi & Trollip, 1991; Hunka et al., 1978) is that some of the most valuable feedback about the quality of a CBI course and ways to improve delivery comes from the student. To take advantage of learner feedback the project design includes an option whereby the student is able to send a message to the program authors from within the course.

At any place in the course, the student can select an option to send a message to the course authors. This is then passed to the server as a text file containing the student ID, email address and pointers to the specific location within the program from which the student is sending the message. This allows the authors to quickly pinpoint the problematic course information and make changes that may be warranted. The inclusion of the student ID, and email address gives the author the ability to direct a message back to the student if additional information is required, or to simply acknowledge the feedback or provide clarification to the student if the feedback is based on the individuals misunderstanding of the course content.

Server Failure

Because client/server communication cannot be guaranteed each time a student attempts to log onto the system, or if server failure occurs during a session, the student must be given alternatives to the various scenarios that may occur. A server failure for the student who is starting a course for the first time is not as crucial as it is for a student who has already begun the course. This is because the first time student has no restart data that must be retrieved in order to begin the course.

If the server is not available at logon, a message is displayed informing the student that any restart data will not be available for this particular session. If the server is not available when the student exits a module a similar message is displayed informing the student that the restart data from the current session cannot be sent. The student is then given the opportunity to save this data on a local disk to be used the next time they start that particular module. If the server is running the next time they log onto the system that data is then uploaded to the server.

Lecturer & License Holder

A lecturer would be any individual acting as a course instructor or facilitator. This individual is registered by the license holder and would be the one with the most direct contact with students. Thus, this user level requires the authority/ability to register students, remove students, and change student passwords.

The interface for the student and lecturer are packaged together using the same login screens. If the user logs in as a lecturer an option is provided allowing the user to indicate whether they are accessing the system as a lecturer or student. This provides a lecturer the ability to access student records while in the lab working with the students. It also allows the lecturer the ability to access course materials.

The license holder is the individual or institution that has purchased a license permitting access to server resources. The primary concern of this individual is assumed to be the assigning of course lecturers. However, this individual may also need to register and work with student records. Thus, the privileges and interface are the same as for lecturers with the additional ability to register lecturers. lecturers are not permitted to register other lecturers.

System Manager

The System manager is the individual responsible for the overall operation and maintenance of the system. The primary responsibility of this individual is the administration of the course(s) offered. The system manager is responsible for registering new license holders and ensuring that the most current modules are uploaded to the server. However, this individual is also responsible for ensuring the system runs smoothly by correcting any problems as they arise. This individual should have access to all areas of the server and have the ability to change and/or modify all files and databases therein regardless of ownership. The system manager must be aware of the ethical responsibility concerning modification of private files; however, in the event that these files are causing system failures and/or disruption to the overall performance of the system there must be some recourse available.

The registration of a new license holder initiates two important processes on the server. The first is the creation of a license specific directory. All users associated with this license are given storage space here for personal records when they are registered.

The second is the entry into a central database of the license expiry date. All client requests received by the server initiate a call to this database to confirm that the user making the request is associated with a viable license. If the license has expired a denial is returned to the client informing the user that further information requests will not be accepted until the license has been updated. With this information stored in a single location it is a relatively simple operation to update the license enabling all associated users to once again access the server.

To update course modules the system manager need only indicate the course being updated and the nature of the upload; new module or update. When a new module is uploaded an entry is automatically made into the course database indicating the correct version number and the module is then uploaded. When an update is initiated the database record for that module is read and the version numbers automatically updated to reflect the status of the new module. The new module is then uploaded with the proper version number. The previous module remains in place in the event that it will be needed by a students who have already started that particular version.

Shockwave Comparison Time Trials

As stated earlier, this project utilizes Authorware Professional from Macromedia as the authoring language for the courseware and the user interface. In an attempt to utilize the ubiquitous nature of the Internet, Macromedia have themselves developed a delivery system known as Shockwave®. This method permits developers to deliver their courseware, animations, digital video etc. using a WWW browser such as Netscape and Microsoft's Internet Explorer. Macromedia supplies the software needed to transform a project into a format that can be accessed via the WWW. Although this project and the Shockwave system utilize the same communication medium, preliminary testing has shown there is a considerable time difference in their delivery.

A series of tests were run using a Power Macintosh 8500/120 using a 28.8 baud modem. A portion of the *Understanding Statistics* course was shocked and uploaded to a WWW server. At the same time a program *kernel* containing all the files a new user would need to start the course was compressed into a self extracting file and uploaded to the same server. The timings were logged on the appearance of key elements on the computer screen: the initial login screen, program menu, course module, return to menu and finally the logout screen.

Our tests showed dramatic differences in access times for the various project components. We have also conducted other timings using cable modems and direct Ethernet connections. For the purpose of this paper the modem timings are used as this is the most likely connection used by the public at large. The following table shows the access times using a 28.8 modem.

Shockwave

Login	Menu	Module	Menu	Logout
2.00	**14.50**	**21.20**	**26.14**	**33.35**
0.33	7.00	11.00	15.30	16.20
1.35	7.32	12.10	16.50	18.35
0.33	5.02	9.30	13.40	14.40
2.00	**15.13**	**19.40**	**24.10**	**25.45**
0.34	4.54	9.00	13.30	14.13
1.31	6.45	11.30	15.40	22.40
0.33	4.48	9.45	13.49	14.37

Project

Login	Menu	Module	Menu	Logout
0.10	**15.50**	**18.42**	**19.06**	**19.29**
0.04	0.39	0.54	1.12	1.27
0.04	0.40	0.50	1.06	1.23
0.05	0.38	3.45	3.59	4.16
0.06	**15.50**	**18.41**	**19.00**	**19.18**
0.04	0.34	0.45	1.00	1.15
0.09	0.37	0.47	1.00	1.19
0.09	0.35	3.55	4.00	4.29

These times are cumulative and include entering a student ID and password. The bolded numbers indicate the first run of a test when there are no user files or cache available. The access speeds for both systems dropped dramatically with more files available on the hard drive.

The real advantage of our delivery system, is once the files reside on the host computer very little client/server communication is needed. This is then limited to the transfer of small (32K) packets of restart data. There will be times when a new module or library file is downloaded, but this will only have to be done one time. This is in contrast to the constant client/server communication needed to access the same files with a WWW browser. In all fairness to Macromedia our particular project requires the accessibility of a number of components at any given time. We found the Shockwave worked very well once we had them loaded. However, the latency is unacceptable for a project such as the *Understanding Statistics* course

These test are very preliminary and indicate that more rigorous testing using a variety of connections and hardware are needed. Plans for such testing are currently underway.

Summary

The exponential growth of the World Wide Web and the Internet has brought with it a subsequent flurry of activity as educators try to take advantage of the potential for world wide communications. The relative ease of communicating over great distances makes this a very attractive medium for course delivery. A variety of methods have been employed that include the use of forms in browser based delivery, the use of browser plugins permitting the client to view small applications, text based instruction in HTML format, and computer conferencing. While each of these methods are useful and can be employed to meet specific needs, they fall far short of the potential for CBI. The success of this project allows the designers of CBI to take full advantage of the communication medium offered by the Internet while retaining the strengths inherent to this form of instruction.

Perhaps the single most important outcome of this project is a product that provides for the immediate availability of updated course material without the logistical and administrative headache of sending new CD's or floppy disks to all students taking a given course. Developers of CBI are well aware of the ongoing nature of course improvements and adjustments, many of which cannot be made available to the student presently given the logistical considerations. The project's product ensures that student's registered in CBI courses will always have available the most current updated version of a course.

The storage of student performance records and direct feedback to the course authors provide valuable information to both the student and instructor that ensures course improvements can be made quickly, based upon "real" and current student data. This valuable information had been lost to course developers using CD technology. However, this project provides information analogous to that available on PLATO and it's centralized database system.

The system log file that keeps a record of all server interactions makes it possible to track student activity. Use of this capability may offer researcher a wealth of information about the frequency and duration of student learning interactions and the learning achieved. It would also provide information on areas of the course causing students particular difficulties based on the time it took students to finish a particular module or concept.

Course administration is relatively easy and can be done from any location with an Internet connection. Student rosters are easy to maintain and the indexing system provides all users with individual storage space for course related files. Built in security ensures that these files remain confidential and non-transferable to unauthorized users.

Finally, the license data-base allows the vendors of software a very simple way to control access to updates, while having the opportunity to allow their licensed users to update their license immediately without the need to use international mail systems to transfer electronic media and funds.

Unlike most other forms of Internet-based course delivery, the student is able to work on course materials without an active connection. The absence of an Internet connection only prevents automated module updates and record keeping capabilities. However, with the student able to save restart data on a local disk, this information is available the next time the course is accessed. If an Internet connection is then established, new records may be uploaded to the server for permanent storage and later retrieved

The microcomputer provided developers of CBI the ability to deliver course material to a much wider audience. Our system provides educators the ability to easily administer distance education courses on a world wide level. At the same time this ubiquity is shared by students who can access course materials and personal records regardless of location. The only limitation being the presence of a program kernel and an Internet connection.

Granted, some new problems are also generated. In its current status, the full benefit of this form of delivery is only available to individuals with a continuous Internet connection. This could provide serious financial considerations for the home user that must pay an Internet Provider an hourly rate for their service. A future enhancement will initiate a dial up SLIP or PPP connection only at the onset and conclusion of a given session.

The Case for Database Support in Multi/Hypermedia Application Development and Use

Scott Dynes, MIT Center for Educational Computing Initiatives, Cambridge, USA sdynes@mit.edu

Abstract: As multi/hypermedia applications increase in both complexity and capability, the demands on both the author and authoring tool increase. The case is made that utilizing a database at the core of both the authoring and execution of theses applications eases these tasks in ways which naturally lead to increased flexibility in both authoring and distribution. The database can be very effective in both the production and maintenance of these applications. By connecting to a central database, remote applications can easily update and modify themselves as well as leave information in the central database. These capabilities are especially useful for both local and distance education applications. Two examples of educational applications that use this database-centric model are discussed.

Introduction

Recent advances in computer hardware and software have resulted in increasingly complex educational and entertainment applications which increasingly incorporate large amounts of multimedia data. The usefulness and appeal of these applications is enhanced by using rich sets of links creating order out of these media objects. In the near future, these applications will maintain their relevancy by becoming dynamic, rather than static. This process will require that applications be able to modify themselves.

Typically, such multi/hypermedia applications are developed using authoring tools which use a proprietary scripting language to incorporate media objects and scripts into the application. This manner of storing media objects has two distinct disadvantages: 1) making changes in media objects often requires the authoring tool, and 2) keeping track of large numbers of external media objects (i.e. .jpg, .avi, .mov files) becomes very cumbersome. Finding the name of a specific media file can involve searching many scripts; moving or changing a file name will likely result in a broken application. Additionally, allowing the user to modify the application is often not an option, as the authoring environment is not available to the user.

One obvious but almost entirely untried answer to these difficulties is to provide database support in both the authoring tool and the application. Databases provide many services which authors will find extremely valuable: a mechanism for managing media objects during authoring and providing objects during execution, easy modification of application content, easy re-purposing of existing media and databases, and separation of content and scripts from run-time engines.

The user also benefits from database-centric design. For instance the ability for local CD based applications to access remote databases via modem or the Internet allows for database-centric applications to form an infrastructure that will greatly benefit educational applications. Just as important, the ability to access remote databases provides a natural means for allowing static applications to update themselves, thus becoming dynamic [Reisman 1995]. The database provides the flexibility needed to implement this hybrid CD-Internet application model.

BEST COPY AVAILABLE

The flexibility that database-centric application development and deployment gives application authors is distinct from the advantages that the same database offers the author in the pursuit of the goals of the application. In the first case, the database is used for management and maintenance of the application content, while the latter case uses the database in support of the application itself.

In this and a companion paper [Curtis and Lerman 1997] we make the case that databases serve a crucial role in the authoring and distribution of multi/hypermedia applications. The companion paper describes a virtual database which provides a common interface to many different types of databases: relational, object, object-relational, etc. This is extremely important for integrating both legacy and media object databases into an application. The current paper discusses how they serve to aid in the creation and maintenance of these applications, and secondly, the capabilities they bring to the application help achieve goals important to many educational multi/hypermedia applications. We will outline these advantages, and then discuss our experiences with two applications which were authored and deployed using a database-centric approach.

Database-centric Application Authoring

There are two reasons to author using a database: for managing the media objects and scripts of the application during authoring and execution, and for the benefits that a database brings to achieving the goals of the application. As the number of files that are associated with a single application grows into the hundreds and thousands, keeping track of the type and content of all the files becomes exceedingly difficult. Databases excel at this task, as each file can be indexed by the media type, a description of what it is, what it was meant for, any information that the author feels would be helpful for keeping track of the media. By associating information with the file name, the author greatly eases access to a given media object, since the author then queries the database for the appropriate object, rather than looking through many scripts to find the hard-coded file name.

In a non-database-centric design once the application is complete, the database is used to replace all script references to the objects with the objects themselves. While this seems a reasonable thing to do, there are many advantages to allowing the database to provide objects to the application as it runs. It is much easier to make changes to the media in this model because the content of a database is much more accessible than the content of a multimedia authoring language. Therefore, a user can modify a database-centric application far more easily than one created with Director or HyperCard. Additionally, this "late binding" of content allows for changes to the application at run time: if the text in an application is to be Spanish rather than English, a simple change in the database query will effect this change.

One feature that educational applications need that may differ from other types of multi/hypermedia applications is the ability for an application to track a student's progress through and interaction with that application, and modify its behavior based on that information. A database-centric application provides this capability automatically through assigning each user a separate record that keeps track of such information. The scripts that determines the behavior of the application need only query the database to determine what action to take next.

If one can conceive of an application that depends on a database to serve it media objects, it is a short step to imagining storing the scripts that determine the behavior of the application. If both the content and the scripts of an application reside in the database, then the only role for the application engine is to load and execute scripts. The separation of the execution engine from the application means that any engine that can interpret the scripts and load objects from a database will run the application. This provides independence from any given authoring system: if the Java of tomorrow offers compelling advantages over the Director of today, the task of re-implementing the application is much easier than if the media were hard-coded into Director Lingo, for example.

Database-centric Application Deployment and Maintenance

Most multi/hypermedia applications today are distributed on CD-ROM, due to the size of the media objects, particularly digital video. While a database-centric application would not be any smaller (and would likely be bigger) than a traditionally-authored application, there is one feature of a database-centric application that is compelling: the natural manner in which database-centric applications can modify themselves. To the database-centric application, there is no difference between sending a query to a local database from sending the same query to a remote database, other than the returned data might take longer to arrive. This being the case, updating any number of remote applications that have connections to a central database is equivalent to updating the central database. From this follows the hybrid model of application delivery. For example a distance education application distributed by MIT consists of a database, scripts and an engine on a CD. The teacher may place additional materials on a central database located at MIT. This database can then be remotely accessed via modem or the Internet by the local application. The central database can be queried for updates, which are then stored in a database on the local disk. This model allows what would have been a static CD-based application into a dynamic application that exists in three different databases, one of which is remote.

For educational applications the ability to access remote databases allows tracking of a student's progress as they use the application. The instructor of the course can easily review each student's activities by looking at the appropriate files on the central database. Additionally, this mechanism allows for students to collaborate, as multimedia notebooks can be stored on the central database, while being shared and modified by a group of students. The local application can also be designed to retain information on how the application is used. This information could then be placed in the central database, where it could be used both as feedback to the authors as well as to tailor updates delivered to individual users.

A Database Model for Application Authoring Environments

Today, there are many different types of databases in existence. The most common commercially available database is the relational database, but object-oriented and object-relational databases continue to increase in both availability and popularity.

The drawback to relational databases is that they do not handle complex data types, and therefore media elements are stored as either file systems references or binary data. Object databases allow for much more elegant handling of multimedia or other complex data types. Every database system provides its own proprietary method for interfacing with an application.

Obviously a user will choose a database for a particular application based on attributes such as functionality, availability and price. However, the application author does not want to have to learn how to construct a new interface for every database system that needs to be connected to a new interface. Multi/hypermedia application environment therefore strongly call for a database access solution that allows integrated access to a variety of database system types. Certain application may also find it desirable to connect to multiple databases simultaneously, and so a multi-database solution is required. Unfortunately, no one standard currently exists that covers the wide variety of database systems that it is anticipated will be needed in the authoring environment. The ODBC standard centers on relational database systems, while the ODBMG standard focuses exclusively on object database systems. Application authors may well want to use both types of system. In addition, the functional requirements of a multidatabase interface for application authors have not been adequately addressed.

A virtual database system is one solution to the problem of shared access to differing database types, and it is expected to become a key component in distributed global technology systems in the future. A virtual database provides for a common object data model with which the author interfaces, while transparently taking care of data and schema translation issues that arise between the virtual database and individual component database systems. Since individual database display differing levels of functionality, the virtual database system must provide a flexible interface that allows access to the extended functionality of some databases while providing extra functionality to compensate for the more primitive database systems.

An example of a virtual database module for a multimedia authoring system [Curtis 1996] has been developed at the MIT Center for Educational Computing Initiatives (CECI).

Examples

Two applications have been developed using a database-centric model and the virtual database just described. These applications were authored using MIT's AthenaMuse2 object-oriented multimedia development environment [Harward and Lerman 1994]. In presenting each application, we will discuss the database features used, and relate the difficulties encountered in implementing the database aspects of the applications.

Operación Futuro

CECI is collaborating with Ana Beatriz Chiquito from the University of Bergen to produce Operación Futuro, a multimedia application designed to assist in the teaching of intermediate Spanish to college level students.

The application is divided into three integrated modules. Historia Interactive presents lessons in the form of a non-linear interactive story told over seven consecutive days. The story has several outcomes depending on the student's participatory input. Integrated into the interactive story is also a student work area where traditional exercises and multimedia projects are assigned and completed. The Libro module is an electronic book that is structured into units and includes hyper-linked materials. Text book activities, exercises and assignments draw from the content of the interactive story. The Topicos module is a searchable encyclopedia of information related to Hispanic culture, geography, customs, literature etc. Information from Topicos is also integrated into the electronic book and is available throughout the interactive story.

The integrated nature of the application is possible only because of its database centric design. Each module uses a single database for retrieval of all media and content. This includes the HTML text files for the textbook and encyclopedia, the videos and subtitles used in the interactive story, the thousands of images used in the student work area and even the graphics used to create the application interface. In addition to media, the database will also eventually include the script code for each scene in the interactive story. Since the media used in the interactive story is reused in both the electronic book and in the encyclopedia the three modules can actually be described as three different interfaces to the same database.

The advantages of a database centric design are that it offers an unprecedented level of flexibility to both the teacher and student using the application. For instance in Operación Futuro, teachers can select from existing, or add new materials to the database to create their own customized electronic text book and interactive story. The database will also store information related to the student such as the status of their progress through the interactive story. Assignments given in the student work area can be electronically "handed in" to the teacher. By maintaining a record for each student, Operación Futuro allows for tracking the progress of and grading of individual students.

A database-centric design also allows for remote access of materials. For instance a student living in Montana could take a distance education class in intermediate Spanish by having a local CD containing the database-centric application access the central database at MIT thousands of miles away. The ability for the local and remote databases to easily exchange data enables such applications to easily serve as distance education applications.

While the media that forms Operación Futuro is organized in a manner to effectively instruct users in the Spanish language, the individual media objects could be used for many other purposes by imposing a different organization on the objects. Since each media object has many associated keywords in the database, this reorganization is easily effected. The flexibility of databases is such that this reorganization could be done on the fly.

Operación Futuro was developed with CECI's own authoring tool AthenaMuse2 and is running on a Windows platform.

Long Bow China Archive

The MIT history department, the Center for Educational Computing Initiatives (CECI) at MIT and The Long Bow Group, a non-profit film making organization, are currently collaborating on the China Archive Project, an on-line computer archive of video, image, sound, and textual materials on twentieth-century. The key element to this archive is a legacy relational database, which allows for both users to access media concerning topics of interest, as well as the integration of different media objects into multimedia essays. The preparation of the legacy database for this application posed some interesting problems which will be of interest to authors of similar applications.

The core of the archive consists of over 300 hours of valuable documentary and broadcast film footage collected by the Long Bow Group. The archive material vividly portrays major political events, changes in the rural and urban landscape and the experiences of ordinary Chinese people. In addition the Long Bow archive contains several hundred hours of audio, as well as hundreds of image and text sources. For the study of modern China there simply is no equivalent to this collection.

Recently CECI completed a prototype of the archive that demonstrates its basic functionality and potential. The prototype is divided into two modules. The archive module provides an easy user interface which allows the user to search the legacy database using topics and associated keywords; corresponding media records can then be viewed, read, or listened to and are accompanied by extensive descriptive and source information from the database. The tour module provides a sample of "tours" or multimedia essays that illustrate how the archive materials can be used to construct lectures and/or multimedia essays. In the final project tools will be developed for constructing one's own multimedia essay. Without the database component of this application access to the media in the archive would remain limited, sophisticated searches would not be possible and the flexibility needed for a tour builder would not be present; indeed, the ability to access media from the database is raison d'être of this application.

Work on the China Archive Project began with investigating how Long Bow's existing FileMaker Pro database could be used as the core of the design. In the end, several transformations were required to adapt the FileMaker Pro database for this project. The categories that the Long Bow Group used for cataloging their media (people, places, actions, keywords etc.) had to be compressed into a general keyword list and then associated to one or more general topic categories. This made searches of the archive more efficient. It involved a domain expert deciding on the appropriate categories, and then the programmers performing the necessary merges and links. This issue will likely be ubiquitous when legacy databases are re-purposed for use in multimedia/hypermedia applications. In the case of the China Archive, the original purpose of the database was quite close to what was needed. If this had not been the case, the translation would have been much more difficult.

Other difficulties arose through the necessity of converting the FileMaker Pro database into FoxPro, as FileMaker Pro runs only on the Macintosh platform, while the archive is being developed for the Windows platform. Initially there were difficulties due to the 256-character limits for both FoxPro and our authoring language. Alterations to AthenaMuse2, CECI's authoring language had to be made and a more sophisticated

BEST COPY AVAILABLE

database export utility had to be used which converted FileMaker Pro's text files into FoxPro memos, which have no character limit. Another problem that arose during the conversion process was related to the number of keywords associated with each record. In most cases each record had multiple associated keywords, however in the FoxPro version of the database only the first keyword line was recognized. The solution was to merge each record's keywords into one line.

For the demo, the database contained only the descriptions of the media objects; the guided tours were written in a manner that did not use the database capabilities. For the actual application, the guided tours will be included in the database. The application will allow the easy authoring and addition of additional tours to the database by researchers for their own purposes. These tours could be made available to others if the application is deployed as a web site, or as a hybrid application as described above.

Summary

A case has been made for making databases an integral part of multi/hypermedia authoring tools and applications. The benefits range from providing an easy, robust manner for managing an application's media objects during authoring to the ability to easily update or modify existing applications, either by the user or as a result of connecting to a remote database. This allows for the automatic updating of static applications, resulting in a dynamic application that provides capabilities that are important for distance education applications.

We feel that the flexibility that databases offer an application designer, along with the development of virtual database interfaces, will result in the rapid adoption of database authoring techniques by the educational multi\hypermedia community.

Abstract: This paper addresses the Semi-virtual Multidimensional Distance Learning System (SMDL), which is a technical, pedagogical, and organisational prototype-structure of a semi-virtual university. SDML includes both synchronous and asynchronous learning modes. During the initial stage of our project, we regularly transmitted a lecture from a specially equipped lecture room in one university to an equally equipped lecture room in another university using ATM technology. The project is evaluated with consideration to technical and pedagogical issues. A variety of technical problems could be addressed during the regular transmission of the lecture for the course of a semester. Empirical data suggested that the remote students were appreciating the new technologies, whereas the local students seemed to be somewhat sceptical. Moreover, the organisational problems in setting up a semi-virtual university seem to be vastly underestimated in comparison to the technical issues.

1 Introduction

In Germany distance learning in higher education is not as widely available as in other European countries. Fundamental problems arise for regular higher education due to the accelerating trend towards differentiation, specialisation in many knowledge domains and also because of the growing demand for qualifications. Hitherto existing television- or video-based distance learning facilities have not allowed for highly interactive instruction. With organisational, pedagogical, and technical efforts being combined, advances in telecommunications and multimedia now allow for a comprehensive Semi-virtual Multidimensional Distance Learning System (SMDL).

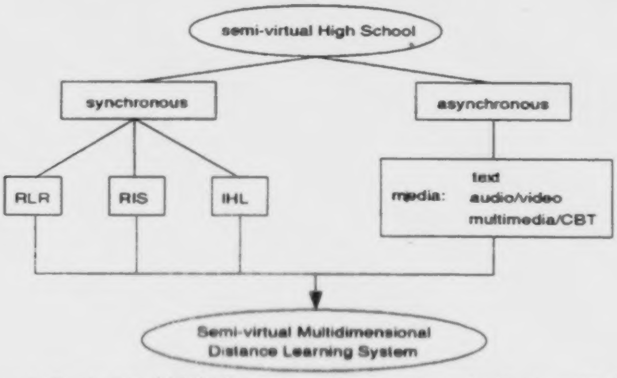

Figure 1: Semi-virtual Multidimensional Distance Learning System (SMDL).

BEST COPY AVAILABLE

SMDL includes synchronous and asynchronous teaching and learning modes as well as multimedia technology [Fig. 1]. In the joint research-project „TeleTeaching" [Effelsberg 95] by the Universities of Mannheim and Heidelberg in Germany, we are currently developing a prototype system of a semi-virtual university.

2 Background and Goals

With both universities situated an hours drive from each other, students have always had to commute in order to gain a sound education in their fields of studies. The Universities of Mannheim and Heidelberg have now formally agreed to enhance co-operation in both research and education. This has provided the organisational basis for a semi-virtual university in which courses will consist of both local and remote (by means through telecommunications) lectures, seminars, workshops, and student cooperative workgroups. Students in the newly founded course of studies „Technical Computer Science", by need of taking courses at both universities, will be the first to take profit in this new educational setting. First trials have been made by providing lectures in computer science and theoretical physics for both Mannheim and Heidelberg students. Moreover, we are using multimedia technology to improve both local and remote teaching and learning. The departments of Computer Science at the University of Mannheim and Computational Physics at the University of Heidelberg conduct the hands-on-business of designing and providing technical resources. A pedagogical and psychological evaluation conducted by the department of Educational Science at the University of Mannheim will gain empirical evidence about the feasibillity and effectiveness of the approach. This will in turn form the rationale behind the ongoing advice regarding the design and use of instructional settings and technical properties.

3 Distance Learning Modules

Figure 1 and 2 indicate three different modes of teaching and learning. We can distinguish between main modules and support modules. The main modules describe the types of instruction to be realised. The support modules are thought to account for an efficient use of the main modules. The main modules are characterized by their scope of distribution, interactivity and individualisation of the learning process [Fig. 2].

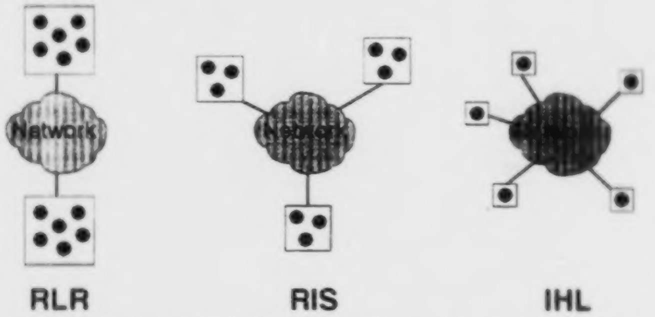

Figure 2: Distribution and individualisation degree of the three main modules

3.1 Remote Lecture Room (RLR)

In the Remote Lecture Room scenario large lecture rooms are connected via a high speed network such as ATM. Each lecture room is equipped with state-of-the-art audio and video facilities and one high performance multimedia workstation. Lectures that are part of the common course of studies of the two universities are exchanged synchronousely between the two lecture rooms. The transmission runs in an interactive mode and we are using the following streams of information:

- The *teacher's video and audio stream*: captured by a local camera and a microphon respectively, these are connected to the workstation. The signals are then digitized, transmitted to the remote lecture room, and

BEST COPY AVAILABLE

projected by a large-scale video projector.

- The *local student's video and audio stream*: are dealt in the same manner, namely the remote students are also able to receive the local student's video.
- The *remote student's video and audio stream* are transmitted vice-versa.
- *Electronic slides of the teacher* and other course materials such as animations, graphics and digital videos are transmitted also by using an electronic whiteboard and shared tools.

3.2 Remote Interactive Seminars (RIS)

In this scenario, small groups of participants are distributed across a few seminar rooms which are also connected by a network. In seminars, students have to formulate and present a report about a certain topic. This kind of learning includes two types of communication:

- *asynchronous*: during the formulation of the report students use e-mail or newsgroups for group work.
- *synchronous*: students are using video conferencing systems to transmit their presentation to the remote groups and use CSCW tools for their group work.

The equipment of the seminar rooms is comparable to the RLR module if somewhat less lavish.

3.3 Interactive Home Learning (IHL)

The IHL module is aimed at the maximization of the geographical distribution degree of all class participants. Each student learns at home in front of his PC. The teacher and the students are connected by low-bandwidth links e.g. ISDN. Asynchronous learning comprises of the retrieval of recorded lectures, lecture notes, work with CBT software and the participation in electronic discussion groups. In the synchronous mode, students should be able to participate interactively and live, in lectures and in seminars whilst being at home. The major goal of IHL is the achievement of better preparation for exams and a further intensification of co-operative learning.

3.4 Teachware Authoring (TWA)

For one hour of CBT approximately 200 hours of developement time are required [Kawalek 95]. Novel approaches such as „Authoring on the fly“ [Bacher & Ottmann 96] seem very promising for reducing the time in effort. We propose the following approach to enhance efficiency in the developement of teachware:

1. *Pre-Authoring* is the preparation of lectures, including all required media sources (slides, images, etc.)
2. *Recording*: The course is given in one of the instruction types RLR, RIS or IHL. The resulting media streams (e.g. audio, video, shared tools, etc.) are then digitally recorded.
3. *Post-Authoring*: Based on the materials obtained from the first two phases, a complete multimedia document, enriched with further multimedia components (e.g. animations) is then produced.

3.5 Multimedia Database Support (MDS)

Storage and retrieval of multimedia teaching material requires multimedia databases. They have to be capable of supporting both discrete media such as text and continuous media such as audio and video media. We propose to combine the capacity of scalable video servers [Bernhardt & Biersack 94] (concerning storage space and real-time requirements) with the ability of hypermedia database systems.

3.6 Telecommunication Support (TCS)

The objective of TCS is to provide the network infrastructure and the communication software required by our three main modules. The live transmission of instruction is based on existing video conferencing systems, which though prove to be less than sufficient for the purpose of teleteaching. We are currently developing a TCS package, which supports group communication mechanisms such as floor control, „putting up hands“, and

BEST COPY AVAILABLE

telepointers [Fluckiger 95]. These mechanisms mainly improve social awareness and the organisation of the geographically distributed group of people working together via computer networks.

4 Pedagogical and Psychological Integration

Quite obviously, the „marriage" of distance and „real world" education [Fig. 1] requires not only technical solutions, but an adequate organisational and pedagogical framework. The pedagogical and psychological importance lies in guiding the users of the SMDL (teachers and students) through design and usability questions. Teachers will need advice in how best to design course materials and handle the technical properties. Students will need guidance in using the material and technical properties, and performing effective learning strategies in both self-regulated and collaborative learning phases. In planning, designing, and sequencing the subject matter of the modules of the SMDL [Fig. 1] we will rely on prescriptive instructional models. The „Learning Cycle" model [Mayes et al. 94] suggests technological and medial options to support the very instructional aims characterizing each of three phases of an ideal learning process (conceptualisation, construction, and dialogue). As each phase corresponds losely to a certain type of instructional setting (lecture, seminar, etc.) the model might prove a valuable framework for instructional advice. We plan to provide our advisory instructions in the form of „learning-by-doing" manuals in combination with (E-Mail-based) tutoring. A thorough pedagogical and psychological evaluation of the SMDL is indispensable for a sound pedagogical and psychological consultation. Our quasi-experimental studies using a multi-method approach are designed to compare local and remote student groups or likewise users and non-users of multimedia documents and programmes.

5 Implementation

The „TeleTeaching" project currently runs in its pilot stage and in the beginning we implemented the RLR module between the University of Mannheim and Heidelberg as described in Chapter 3.

- *Network technique*: The computing centers of the two universities are connected via a 34 Mbps ATM link [de Prycker 93]. Each lecture room is connected to the computing center via a dedicated 10 Mbps Ethernet segment and the university's 100 Mbps FDDI ring. We are currently using the Internet protocol stack on top of ATM, Ethernet and FDDI. This proved to be rather disadvantageous because resource reservation is not possible with IP, consequently, we had to share the link with other network traffic between and within the universities (see Chapter 6). However, to provide high quality video and audio streams a certain quality of service by the network, e.g. a guaranteed bandwidth, is required.
- *Application software*: Currently, we are using the Mbone toolset (Multicast Backbone) for the transmission of lectures, namely *visual audio tool (vat)*, *video conferencing tool (vic)*, *whiteboard (wb)* and *wbimport* [Macedonia & Brutzman 94]. Vat allows for the transmission of telephone quality audio signals using e.g. PCM encoding. Vic provides coding, compression and transmission of captured video streams. It supports compression schemes such as H.261 or M-JPEG. The slides or the multimedia teaching materials are sent to the remote site by using wb. Wb is a shared drawing tool which allows the display of postscript pages to the remote students. Combined with wbimport it offers a comfortable access to all postscript slides used in a lecture. Furthermore, we developed a small tool that allows the electronic „putting up of hands".

6 Experiences

6.1 Technique

In the summer of 1996 we transmitted a complete course about computer networks consisting of 22 sessions from Mannheim to Heidelberg for the first time. From the technical point of view our experience was rather positive. Specifically the software proved to be very stable because we had no single failure. We have been able to minimize the preparation and set-up time of a transmission, due to the fixed installation of all required facilities in the lecture rooms. It is now possible to start transmission within 15 minutes. We did not encounter problems with the whiteboard, however problems arose with the audio and video streams. For the video channels we used the H.261 encoding standard with a frame rate of approximately 16-17 fps corresponding to a bandwidth of about 500 to 600 Kbps. Higher rates could not be achieved with the software codec (coder-decoder) on the multimedia workstation. Thus, we reduced the frame rate of the remote students to 1 fps because the teacher's video is most important. Using the built-in hardware M-JPEG codec allows for frame rates of about 25 fps in TV quality but consumes up to 4 Mbps of bandwidth. We discovered that such a high bandwidth overloaded the connecting network and thus produced severe audio problems e.g. drop-outs. Even when using low-bandwidth video (H.261), from time to time we encountered audio and video drop-outs for a duration of about 2-3 seconds. Experiments showed that during these phases data losses of approximately 87% occured. The reason for this is mainly that it was impossible to reserve a guaranteed bandwidth on the network connection. Heavy network usage of other network users thus produced data losses. Another reason for the drop-outs is the high amount of active network components (such as routers and bridges) on the network connection between the lecture rooms. These components, not thought to transfer multimedia data, additionally introduced delays and losses. Since we were successful in solving some of the problems, the first experiment with RLR can also, from a technical point of view, be considered as rather successful.

6.2 Pedagogical and psychological evaluation

We carried out four surveys, one at the beginning, two in the middle and one at the end of the semester. The two middle surveys were carried out before and after the lecturer temporarily moved from Mannheim to Heidelberg. With this variation it was possible to observe both student groups under the two quasi-experimental conditions. Moreover, the lecture was accompanied by observations and interviews on both local and remote sites. Data was gathered on motivation, concentration, problems in understanding, acceptance and technical aspects etc. In addition, the lecture was evaluated using a standardized questionnaire [Rindermann & Amelang 94].

6.2.1 Students

The data is not yet fully analysed and as yet only descriptive statements are possible. First results suggest, that

- the students' ratings concerning the quality of the lecture are rather high in all criteria.
- both local and remote students were able to concentrate and understand the content of the lecture.
- audio combined with the whiteboard were most important for the transmission of learning contents concerning understandibility, whereas video mainly intensified the social enrolment [see Bacher & Ottmann 96], [Kawalek 95].
- the remote students accept the new technology, but were discontent with some audio and video problems in the beginning of the semester.
- there are differences between the student groups, in that Mannheim students constantly give lower ratings in acceptance of the technology. This tendency becomes even more salient in the data gathered whilst Mannheim was in the remote situation. Interview data suggests that this is mainly due to the higher level of noise in the lecture room with the lecturer not being physically present and hence the fear of not understanding all the relevant information.
- the interactivity was low on both sites. Questionnaire data suggests that students did not feel the need to pose more questions or engage in discussions on both sites, which is quite usual for lectures. Remote students, especially, felt that the threshold for starting an interaction was quite high because they would have to use a microphone and interrupt a distant lecture.
- organisational and informational shortcomings might be the core-problems in setting up SMDL. On average, only about 9 students in Heidelberg (as compared to about 90 in Mannheim) regularly attended the lecture. Interview and questionnaire data suggest, that this might be partly due to the fact that the field covered by the lecture was a specific field in Computer Science, hitherto only established as an original course of studies at the University of Mannheim. Heidelberg students attended the lecture as a subsidiary subject for physics or mathematics lectures. But there is also evidence especially from interview data, that most of the students merely „stumbled" over the lecture in the WWW or were informed by word of mouth. Moreover, the students appeared to be quite unsure about whether there was a possibility for passing an exam in the field covered by

BEST COPY AVAILABLE

the lecture. However, it was highly relevant for Mannheim students. Most of the Heidelberg students did not know about the universities' formal agreement.

6.2.2 Lecturer

As the lecturer was an expert in Computer Science, he become used to using the technology quite easily. The situation of speaking in front of a camera to students not physically present, made him feel rather uneasy at first. In a more interactive instructional setting lecturer-training might be required, especially if he/she is not as accustomed to using computers for teaching purposes as the „pioneer-lecturer".

7 Conclusion

We presented a Semi-virtual Multidimensional Distance Learning System (SMDL). The three modules - Remote Lecture Room (RLR), Remote Interactive Seminars (RIS), and Interactive Home Learning (IHL) are the basis of a semi-virtual university. The initial phase of the SMDL was successful from a technical point of view. The new technology appears to be accepted by students, but it is capable of improvement as far as interactivity is concerned. The fact that Mannheim students constantly rated the experiment lower in most of the criteria might be due to different motivational orientations. The lecture was very important as the Mannheim students had to pass exams in their chosen fields of study. Any technical „fooling around" might be at their expense. A major pitfall for the success of the approach can be seen in insufficient organisational efforts. Therefore, analysing the demands of the teleuniversity in advance, in accordance with comprehensive information and marketing efforts, might prove to be the key to getting SMDL started. Recently, we have begun to conduct seminars in the RIS module and first observations are promising. The IHL module has also started by creating the organisational framework. Furthermore, we are now developing more adequate and user-friendly teleteaching and -learning software, which should be suitable for all modules.

Abstract:. This paper describes the development of a metric for Windows 3.x computer skills. The metric consists of a Usage and Skill Level Inventory and a Computer-based Skills Test. The Usage and Skill Level Inventory rates previous experience of using Windows 3.x programs and generic Windows skills. The Computer-based Skills Test is a set of trivial tasks designed to reflect Windows skill. The two parts independently assess self-declared experience and actual performance in Windows. The results of the evaluation of the metric so far suggest that for the group of higher education teaching staff there is a significant ($P<0.05$) correlation between Inventory score and performance in the Skills Test, whereas for students the correlation is non-significant. Explanations for this disparity are explored and recommendations are made to improve the metric.

Introduction

Work at University of Wales Institute Cardiff in hypermedia authoring has focused on the development of ***SHAPE***© - a **S**emantic **H**ypermedia **A**uthoring **P**ackage for higher **E**ducation which is designed to use concept mapping techniques to reduce the cognitive overhead of expressing a knowledge domain and produce a skeletal hypermedia knowledge corpus which can be 'fleshed out' by the addition of multimedia materials, e.g. text, graphics, video clips [Elliott et al 1995], [Elliott et al 1996]. ***SHAPE***© has currently been produced as an interface to the standard authoring package Asymetrix ToolBook™ which is a Windows-based product. Thus, in evaluating the ease of learning and ease of use of ***SHAPE***©, one runs into problems associated with the transferability of Windows skills. Windows, like other graphical user interfaces (GUIs) e.g. Macintosh Desktop, was specifically designed to provide a consistent user interface using menu symbols or names already familiar to the user to facilitate more rapid learning [Foley et al 1994] and thus Windows experience/expertise was an independent variable which needed to be controlled, since subjects with a greater Windows experience should be better able to engage with a new Windows-based program more rapidly.

This paper describes the development of a metric for assessing an individual's Windows skill. The metric, Computer Skills Metric for Windows (CSM(Windows)), is defined here as a person's transferable skill of using Windows and Windows-based packages, excluding Windows 95 and Windows 95-based products on personal computers. Van Vliet et al [Van Vliet et al 1994] point out that there have been a number of attempts to develop tests to measure computer skill, although each is intended for particular subject group and computer skill. In their experiment Van Vliet et al found that self appraisal tests used alone can introduce a leniency bias where subjects inflate their own skills and Van Vliet et al concluded that to get a true picture of skill, a number of different measures should be triangulated to give a more accurate assessment.

Definition of Computer Skill

A simple definition of skill has eluded both behavioural and cognitive psychologists although defining characteristics of skill include: a wide behavioural domain in which behaviours are assumed to be complex; an understanding that skills are gradually learned through training; and attaining a goal is dependent upon motor behaviour and processes. Gattiker [Gattiker, 1992] categorises the meaning of the term 'skill' in relation to its potential ease of transferability and reasons that computer-interface-skills have low transferability.

Each individual is equipped with innate motor behavioural abilities and an ability for cognitive processing (abstract reasoning, problem solving, etc.) which they can develop generally or achieve specific tasks/jobs.

CSM(Windows) measures both motor-behavioural (e.g. mouse and keyboard) skills and cognitive process abilities (e.g. finding/knowing the correct icon, command sequences, menus). Subjects with a high skill level in Windows generally, should be able to rapidly orient themselves in an unknown Windows program, provided that the objective of the unknown program is fairly easy to understand.

From observations of four cohorts of students taking a course in basic computer skills over a four year period a list of elementary skills for using Windows and Windows-based packages has been compiled:

Psycho-motor skills:	Cognitive Processes:
• Single click with left mouse button • Double click with left mouse button • Drag and drop • Select from button types, menu options, dialogue boxes as required • Input via keyboard	• Successfully carry out a sequence of the above activities to complete a task e.g. draw a shape on the screen • Learn a sequence of the above activities to complete a task • Search for assistance to carry out an action and follow instructions • Understand/create/update/delete file and catalogue structures • Understand salient aspects of hardware: hard drive; floppy drive • Understand the 'computer processing paradigm': the limitations of computers; their apparent pedantry; and the necessary sequence of operations

The CSM (Windows) Metric

The metric is computer-based and has two parts: a Usage and Skill Level Inventory, and a Computer-based Skills Test (a battery of 5 exercises that aim to test the list of motor-behavioural and cognitive processing skills above). The philosophy behind the inclusion of an inventory and a test-battery was that each part could help validate the other.

Usage and Skill Level Inventory

This is designed to find how extensively subjects use Windows and Windows-based applications and is completed by the subject under the supervision of the researcher. The inventory asks salient questions about the subject's experience in terms of experience of using Windows and Windows-based applications. It is recognised that even if a subject uses Windows all the time they may still have a low skill level.. The last inventory question asks subjects about their perceived skill level is on a scale from None to Very High.

Computer-based Skills Test

The exercises are monitored exercises which incorporate typical Windows-based tasks. Whilst it is recognised that the exercises also test other cognitive factors, such as problem solving skills, the tasks are designed to be trivial as possible with simple instructions printed on the screen to reduce cognitive overhead. The underpinning hypothesis is that subjects with prior Windows skills should complete more of the exercises more quickly than those without. CSM (Windows) calculates the time taken and the percentage of each exercise completed.

Use of help facility

A standard help facility is available throughout the exercises to help subjects complete them although no help is given on basic Windows skills. Use of the help facility is seen as an important Windows skill so any use of the help menu, particularly in exercises 3, 4 and 5 which are more complex exercises are counted and registered by the system.

BEST COPY AVAILABLE

The Exercises:

The exercises attempt to measure different aspects of Windows skill however it was anticipated that there would be some overlap of these aspects. It was therefore of interest to see the extent to which the results of the exercises co-varied. Significant covariance between the exercises would suggest that one exercise could be substituted for another if necessary. The table below explains what each exercise is designed to measure.

	Tests ability to:
1	'Drag and drop'. The cursor changes when dragging the shapes which is a familiar Windows requirement. If subjects do not know how to 'drag and drop' they will not be able to complete this exercise.
2	Click to move the cursor into the text entry box and keyboard knowledge. Subjects are asked to copy type a short paragraph that includes some of the less commonly used keyboard characters that require the use of the shift key, etc.. The time to complete this exercise should be directly related to typing ability (for non-typists). The program measures any mistakes that subjects make in carrying out the task.
3	Construct objects on screen, using a series of commands and pull-down menus / tool-buttons / mouse - activities.
4	Carry out a sequence of activities using a command-driven interface. This exercise attempts to test a subject's understanding of the computing paradigm, i.e. the logical sequence of activities and the need for precision in syntax in specifying an action/command. Subjects with a background in general computing should be able to carry out this test better than those who without.
5	Carry out a bogus task using a number of standard Windows features: double-clicking; restoring and minimising objects; using option buttons and sliders; selecting files. Although subjects will not understand the task they should, if they are proficient at using Windows, be able to carry it out. CSM (Windows) measures which elements of the exercise has been completed

Procedure

CSM (Windows) has been used by 97 subjects to date, 74 first year students who had just completed a course in basic computer skills and Information Technology and 23 higher education lecturing staff. The program was administered to the students in a computer laboratory and they were told that the results were confidential, would only to be used for research purposes and would have no effect on their assessed mark for the course. The program was administered to lecturing staff in a similar fashion with the assurance that the results were confidential and would be used for research purposes only.

Results

The results are presented as a comparison between the two subject groups because of the differences observed between them.

Reliability

A Cronbach alpha test was carried out on the two parts of CSM(Windows) and the results showed that the Inventory was reliable, probably because it has so many component elements, whereas the exercises are less reliable, probably because there are only 5 elements.

Usage and Skill Level Inventory

Table 1 shows the median and interquartile range (IQR) for experience for the use of Windows and Windows-based programs for staff and student groups. The higher the median score the higher the experience and self-declared expertise in that area.

Correlations between the exercises

Some of the between-exercise correlations for exercise times for staff (between exercises 1 and 2($r=0.66$), 3 and 4 ($r=0.80$) and 4 and 5 ($r=0.45$)) and students (between exercises 1 and 2 ($r=0.29$), 2 and 3 ($r=0.28$), 2 and 4 ($r=0.31$), 3 and 4 ($r=0.31$) and 4 and 5 ($r=0.28$)) are significant ($p<0.05$). There were very few significant correlations between the exercises for fraction-completed.

Use of the help facility

Table 4 below shows the mean number of times help used and its correlation with the inventory score for each subject group

	Staff	Students
Mean usage of help facility	4.30	6.55
Standard deviation of usage of help facility	6.50	6.62
Correlation of use of help with inventory score	-0.09	0.03
Significance of correlation of use of help with inventory score	0.67	0.80
Correlation of use of help with overall completion Rate	0.39	0.22
Significance of correlation of overall completion rate	0.07	0.06

Table 4: Mean number of times help used during exercise and correlation with the inventory score for each subject group

Discussion

The staff inventory scores covered a wider range of values than the students even though the sample was smaller. This is not surprising since the students (mean age 20) represent a more homogeneous group with less overall experience of computers. The application skills were similar for both groups, however staff had greater experience in email, other Windows programs and Windows utilities. The responses to the questions appeared to be a fair reflection of both groups computer experience. The differences between the overall inventory scores was not significant because of the wide variation of the staff group and the homogeneity of the student group.

The differences between timings for exercises 1 and 2 for staff and students was not significant, however it was for the other exercises. The differences between the fraction-completed for staff and students for all exercises were not significant, indicating that although their timings for the exercises differed they did not complete anymore. All subjects completed exercise 1 and the timings correlate with the inventory score significantly for both groups, indicating that exercise 1 is a measure of a subject's Windows expertise. Students spent considerably more time trying to complete exercises 3,4 and 5 than did the staff. This may be because the students felt that they were 'competing' with their peers and did not want to be seen to have failed whereas the staff seemed more circumspect about their performance. Another reason might be that since the average age of the staff group was greater ie less 'attuned' to computers and the group had proportionally more low inventory scores so they were less confident and gave up quicker. Another confounding factor could be that this group of students had just completed an introductory course in using Windows-based programs. These factors need further study.

The times taken to complete the exercises 1 and 2, 3 and 4, and 4 and 5 co-varied significantly in both groups. There was a significant correlation for fraction-completed for the student group only between exercise 4 and 5. The picture for the staff group is very different with significant correlations between exercise 3, 4 and 5. These covariances point to overlaps in the skills being meaured and will require further analysis isrequired to explain the observations.

Students were more inclined to use the help facility than staff suggesting that they were again more confident in using computers. There was no correlation between use of the help facility and inventory score and use of help and completion rate for either group, suggesting that use of help is idiosyncratic and does not have a bearing on the success of subject in a new computer situation.

The correlation between student performance in the exercises and their inventory score was not significant, but it was for staff. Accounting for this discrepancy is difficult - if the exercise were badly designed one would not expect a high correlation for either group. If the exercises are viewed simply as problems, one might expect subjects with good problem solving skills to do better. A measure of the students' generic problem solving skills is not readily available, however performance in an assignment not closely related to computer skill has been made available. This assignment required students to analyse the information technology needs of a known organisation. The correlation between their performance in this assignment and the fraction-completed of the exercises is significant ($r=0.33$, $P=0.005$). Interestingly there are no significant correlation between their assignment mark and the inventory scores, use of the help facility and the times spent on each task, suggesting that it was the students' problem solving skills that largely dictated their success in the exercises and not their experience in using computers. Subjects were asked to rate their overall skill from none the very high in using Windows, this correlated significantly for both groups with the inventory score (students $r=0.66$, $P=0.00$, staff $r=0.93$, $P=0.00$)indicating that their answers were consistent and supported by the reliability analysis.

Conclusions and further research

Both students and staff seemed to be honest in their answers to the Usage and Skill Level Inventory which reliably reflects their usage and skill in using Windows and Windows-based packages. Although, as [Von Vliet et al 1996] note, there is a danger of an inflationary bias in the results of self-appraisal tests if they are to be used for a formal evaluation of performance. There was a good correlation between staff inventory scores and their performance in the exercises but almost none for the students. A possible explanation for this may be that students are more comfortable with computers than staff, are more tenacious and more willing to experiment. Another reason might be that Windows has become transparent to the students and it is only their problem solving abilities that are being assessed.

The degree to which Windows is transparent to students and the exercises only measuring problem solving skill needs to be explored. The co-variances between the exercises needs to be further studied to discover what are the overlapping components of Windows skill. The lack of correlation between the use of the help facility and performance in the exercises for either group is a salutary lesson for help facility designers and could be investigated further.

CSM(Windows) will be re-examined and refined following this initial evaluation, but the usage and skill level, inventory has been found to be a good measure of a subject's experience of Windows.

Abstract: The Internet is arguably the most important development in educational technology in recent years. Major changes in the use of the Internet within universities presents many challenges for the management of IT infrastructure. This paper reports the results of a survey of IT Directors of Australia's 38 universities. The survey addresses aspects of provision of Internet services both on and off-campus. It analyses the varying strategies that have been adopted in meeting demands for services such as modem banks and laboratory access. The paper shows that there have been rapid changes in the quantity and quality of services over the last two years. It discusses the near universal concerns of IT managers about the impact of the Internet on cost structures and on their ability to continue to provide more traditional services.

Introduction

It is widely accepted that information technologies in general and the Internet in particular are an increasingly important element of the teaching/learning environment of Universities. The impact of information technology is leading to fundamental change in the nature of the University. Eli Noam, Director of the Columbia Institute for Tele-Information at Columbia university sees that the application of IT making the need for self-reform in universities an urgent task. Such reform:

> ... *may include a far-reaching structural administrative reorganization, breaking up the university into its component functions - credentialing; guidance; knowledge generation; instruction; and housekeeping. There will be a significant outsourcing of the latter two functions. There will also be an export of electronic courses beyond the traditional student population. In course provision, we will see much less of the traditional lecture system, which is a very inefficient way to accomplish the information transmission function of education. We will also see, in successful universities, an expansion of the guidance function, more of the tutorial, hands-on, mentoring-type activities that direct human contact provides best.* [Educom Staff, 1996]

He sees that the impact of information technology will particularly fall on the larger, publicly funded universities. [Hamalainen, Whinston, & Vishik, 1996] assert that "as perhaps the world's largest information industry, education is set to adapt a new just-in-time, on-demand approach to delivering its products through virtual universities by way of the Internet administered through the technology of electronic commerce". A number of models for the production and distribution of education are discussed. The impact of new models of networked empowered education will lead to changes not only in the delivery of education but also in more prosaic areas such as payment systems.

The management of the Internet and IT in Universities

Not only are academic planners seeing major changes in education arising from the Internet. Students are increasingly demanding access to Email and the World Wide Web. These tools are firmly embedded in their learning experiences but perhaps more importantly, are a well established part of their popular culture. A key element in the response of the University to these changes will be the planning and management of Internet infrastructure development. Depending on the infrastructure model adopted there will be implications, such as the transition from traditional modes of face-to-face teaching to an Internet enhanced model, for the 600,000

BEST COPY AVAILABLE

students currently enrolled at Australian universities. These changes are against a background of constrained University budgets.

A linked array of possible activities are involved in the creating the Internet enhanced teaching and learning environment. These include the preparation and delivery of materials by faculty, the access to wider network resources and the use of those resources by the student body. In addition, students and faculty interact in a number of ways. These are shown in [Figure 1]:

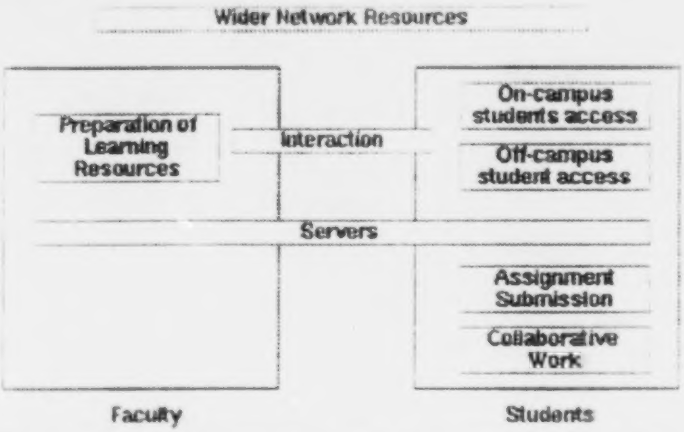

Figure 1: Model of the Internet enhanced teaching and learning environment

This mix of services can almost be seen as a Rubik's cube. Initially services were provided only on-campus and only to staff. This is represented by the front, top left hand element. A very limited number of Universities have gone on to develop an infrastructure which extends provision to all elements of the cube with an example being Boston University's Project Agora (see EduPage, 24 June 1996). Other Universities have adopted an infrastructure which supports only some elements. The purpose of this study is to analyse the response of Australia's universities to these changes.

The Survey

Universities in Australia, as elsewhere, are grappling with tremendous growth in the demand for access to the Internet, from students and staff; exponential growth in Internet traffic from their campuses; demands for alternative access points to the network around the campus and for the provision of off campus services for staff and students. The situation is highly fluid with Universities adopting many different models. There has been no comprehensive mapping of the provision of services, the management strategies and the forward projections for meeting these demands. This study reports the results of a survey of all 38 Australian Universities in terms of their present Internet provision and their planned provision in both the short and long term. The target population was Australia's 39 universities, two of which are privately funded. For full names and contact details the Australian University Vice-Chancellors' Committee maintains a link to all university web sites at `http://www.avcc.edu.au/uniwebs.htm`

The survey was approved and then distributed by the Committee of Australian Directors of Information Technology (CAUDIT) (`http://www.curtin.edu.au/other.caudit/information/`) with the expectation that directors themselves would complete the details.The survey took the format of approximately six screens of a World Wide Web mounted form. The form contained 86 questions of which 59 were "click and select" responses and 27 involved "type in text boxes" responses. Data submitted on the form was processed by a CGI script and then subsequently analysed in spreadsheet and statistical packages.

Reminder notices were sent via email on two occasions and within eight weeks from the release of the survey in mid-December 1996, a total of 29 responses (74%) were received. In comparison with a similar mailed questionnaire, this response rate was high. The Web format also provided flexibility in the design of the questionnaire and delivered the data in an electronic format ready for analysis.

Results

Introduction

The 29 responses received via the Web were representative of the range of size and geographic locality (city versus regional) of Australian universities. Further, the IT directors were diligent in that the surveys were, with a few exceptions, complete. This was a function of the design and return mechanism of the survey. In the following sections we analyse the results from the major sections in the survey.

University IT Planning

We asked universities for details on whether they had developed formal plans for Information Technology and if they had, the date on which the most recent version was published. Seventeen (17) had developed plans with 12 either not having plans or in the process of developing a plan. Most of the plans were current for 1996 but a couple dated back to 1990/91. Our survey data indicated that none of the plans were available on the World Wide Web.

Undergraduate Laboratory Connectivity

A major focus of the survey (43 questions) was the provision of Internet services for undergraduate students. All universities provided undergraduate students with email accounts. Some 18 of the universities automatically create the students' email accounts. The remainder create the students' accounts upon request. Only one university allowed the students to keep their email accounts after graduation. It is perhaps surprising that more universities have not recognised the potential of long term electronic linkages between their recent alumni and the University. This is a statistic that may change rapidly in the next few years.

Most universities manage their student email centrally. A total of 19 universities provided a response on the level of hard disk storage provided to students for their email. The minimum storage provided was 0.1mb with the largest being 10mb. The median storage supplied was 1.5mb. One large city university dispersed the email down to local area networks within the faculties.

Half of the universities (14) allow students to generate their own World Wide Web pages. This is a higher proportion than might have been expected given the recent arrival of the Web. Ten (10) of these provided details of the amount of storage provided to students to store their Web pages. Storage levels seemed to be generous with the minimum allocation being 1mb and the maximum 10mb per student. The median storage facility was 2mb. These levels of storage allow for quite complex student home pages. Again, for the single large city university discussed in the previous paragraph, storage was delegated down to the faculty level.

All but two of the universities had Internet connectivity in their undergraduate teaching laboratories. One of these indicated that connectivity would be complete in 1997 and the other stated that connectivity would be coming at a later stage. It is presumed that these universities would have a mixture of labs that were and were not connected to the Internet. All but one of the universities providing Internet access to the undergraduate laboratories also provided Telnet access.

All universities with Internet access also provided World Wide Web connectivity. This is again surprising given the recency of the technology and the hidden cost implications. While the essential browser software is freely available for Universities there are other financial implications. PCs that would have had perhaps only 4 or 8mb of RAM in the past, must now be upgraded. The university network backbones must be ramped up to meet new demands in terms of protocols and volumes of data being transferred.

The ability of the Web to readily incorporate multimedia features of sound and animation has been a major factor in its rapid diffusion. Some of the most interesting material of educational value on the Internet is in RealAudio and other audio formats. The survey sought information on the capability of computers within the laboratories to play audio. Eleven universities had laboratories which were currently "sound capable" with a further three universities planning to add this feature in 1997. Seven universities were planning for this feature at a later stage and a similar number were not considering this provision at any time. Of those that currently had audio capabilities, only three reported that headphones were provided in the laboratories. Clearly this statistic will increase in future years.

The survey asked if the Web browsers were capable of displaying animation (e.g. Shockwave or Java). Fourteen (14) reported that these features were supported, with 12 advising that this would be added in 1997 or later. This is a strong indication that there is a priority in upgrading Web browsers to support the most recent advances in Web technology.

Undergraduate Non-laboratory Connectivity

The survey asked a number of questions about connectivity outside the traditional computer laboratories within the University campus. Twenty-one universities currently have Internet access in the library with a further two major city universities planning to add access in 1997. A further five universities plan to add access at a later date. Interestingly, the integration of library functions and the Internet is not seen universally as being a priority.

An increasing number of students are acquiring laptop computers. The survey asked for details on the provision of high speed (Ethernet) "docking stations" for laptops. Four universities currently provide this service; another university plans to add the service in 1997 and 16 at a later date. Surprisingly seven universities have no plans for docking stations.

Most universities in Australia have residential colleges or some other form of student residences. The survey sought responses on the number and nature of connectivity supplied to these facilities. Twenty-five universities currently provide at least some residences with network access. Of these ten provided less than 100 connections. Most connectivity was via Ethernet with only two universities reporting that connectivity to the residences was over a dial up service. When questioned about the issue of limiting individual access times, twelve universities indicated that this was already current practice with a further 10 universities indicating that it was under consideration. Clearly the trend is to limit the load on the network.

Off-Campus Availability

Australian universities service a relatively high proportion of part-time and external (distance education) students. The survey therefore addressed a number of questions on dial in access. In 1996 only four universities offer more than 200 modems and seven provide less than 50. By commercial ISP standards none of the universities are providing modem banks of a sufficient size to allow "unlimited" access.

We tested the relationship between size of institution and the number of modems supplied for student dial-in access. As can be expected, there was a statistically significant relationship between these variables. A one-way ANOVA showed that size of institution could only explain 29% of the variation in the dependent variable of the number of modems. It was significant at the 99% confidence level. Looking at the data, some interesting patterns can be observed. Some smaller universities have clearly made substantial investments in modem banks. At the other end of the scale there are very large universities which have apparently made decisions that they can provide only token access. This is illustrated by four universities. Summary information on these selected institutions is shown in [Figure 2]:

University	Type/Size of University	Students	No of Modems
A	Capital city, small to medium size	5-10k	101-150
B	Capital city, large	15-20k	0-50
C	Regional, small to medium size	5-10k	> 200
D	Regional, medium to large	10-15k	0-50

Figure 2: Provision of Modems by Selected Universities

The pair of city universities have adopted different strategies. University A has a large number of modems for its relatively small size. B has effectively decided not to provide modem access. In the regions, C would appear to have adopted a strategy that provides extensive modem access for students while D has adopted the reverse approach.

As might be expected there is a clear trend to provide modem banks that provide the highest speed of connectivity that current technology will provide. Thus in 1995 the majority of external modem banks had less than 25% of 28.8kb modems. In 1997 half the universities have only 28.8kb modems. This demonstrates that a relatively rapid response has been made to the bandwidth demand that is primarily being driven by graphical web browsers.

Modem dial-up protocols have been rapidly adopted within the University community. In 1995, 12 universities provided PPP access with 14 providing other forms of access such as SLIP and direct connections to minicomputers. In 1996 this had changed to 22 and 4 respectively.

Access to modem banks is a function of the demand and of supply factors including the numbers of modems provided and any limitations imposed on users' connect time. By 1996, 19 universities reported that limitations on student access time were in place. Another option to control student access which also reduces charges on Internet volumes to universities is to limit student downloads of data. Surprisingly, only six universities report that they limit downloads.

The survey also requested open-ended responses on the provision of Internet access to off-campus undergraduate students. The responses received are summarised in [Figure 3]:

Type of Provision	Number
No provision	8
Arrangements with Internet Service Providers (ISPs)	4
Modem pools at regional campuses	6
Dial in to central modem banks at student expenses	4
Other	2
Total	24

Figure 3: Provision of Off-Campus Access

A trend can be seen from these responses. The 6 universities which are providing modem pools at regional campuses are all either "network" institutions which have resulted from the merger of a number of smaller institutions or which have a substantial proportion of distance education students. For other institutions, encouraging students to gain access to the Internet via ISPs is increasingly popular and will be discussed in the next section.

High rates of growth of traffic are being experienced by universities in Australia as evidenced by the statistics shown at `http://www.avcc.edu.au/avcc/aarnet/trafrec/memtraf.htm`. This growth translates into higher charges to individual universities. The survey sought information on cost recovery. At present 6 of the 25 universities which answered this question were levying charges on off-campus Internet access by students in 1996. Of course, a number of those universities which are not making charges are also providing limited or no Internet access. Charging mechanisms varied widely. Annual charges ranged from $50 to $80 per annum. One university charges the teaching units for legitimate usage of the Internet and private usage is charged to the student. Considerable change in charges to students can be predicted to occur over the next year or two. The survey asked if the university was considering changes in its charging mechanisms in 1997. Fifteen (15) advised that they were considering changes with 10 not considering any change. These changes will result in 18 universities making charges for off-campus access in 1997 with 7 making no charge. This is an almost exact switch from the 1996 pattern. As one director stated, "we cannot face continued growth at 17% per month".

Moving students from dial up access provided by the university to Internet Service Providers (ISPs) is seen as reducing cost and potentially providing a better service to students. The cost of those services is then placed on the student. A variety of support for ISPs was evidenced. Some universities maintain lists of suggested or recommended ISPs. Others have formal relationships between the university and an ISP. Formal relationships were in place at 10 of 28 universities in 1996. Seven (7) of the universities that did not have such relationships were either actively pursuing this option or were ready to sign an agreement. One regional university reported that it had had difficulty in finding ISPs that could adequately meet its technical requirements across the country. One medium sized capital city university advised that it had rejected the ISP concept as it was too expensive for students. There was clearly no enthusiasm amongst the survey respondents to provide large scale off-campus access for students and especially for undergraduates.

Discussion

The responses to the survey indicated that directors of IT feel that the Internet is creating many challenges for the provision of general and specialist computing services. The survey requested that they respond to the question "what is your single most important concern for Internet provision in 1997?". Sixteen of the 23 directors that answered this question said that the single most important concern was cost; or as one director of IT at a smaller university stated "Cost! Cost of data, cost of links, cost of machines capable of running the 'latest and greatest'". Another director said that desktop resources are being consumed for searching for information on the Internet with "less availability for previous desktop activities". Others were also concerned with an explosion in Internet activity for other than scholarly purposes. One director of IT at a large city university recognised that "we can develop a lot of what we have to offer using the Internet" but that there was "A lot of use [of the Internet which was] not for serious scholarly work, how can this be controlled?".

Another concern which was expressed by regional universities was the provision of access to distance students. The director of IT at a large provider of distance educaiton noted that a particular concern was "access for remote students (as opposed to those who are external)". The director noted that the "lack of equitable access in both cost and quality of connection appears to be impossible to overcome for many students". Equally, there was concern that the Internet was eroding the more traditional role of IT in universities. A number of directors stated that they considered that internal charging mechanisms within the university was the only solution to decisions on what resources were to be allocated to the Internet in the teaching and learning process.

The survey has shown some trends which might have been expected. Growth rates in usage of the Internet are clearly causing IT directors major management challenges. These are being responded to, at least in part, by moving undergraduates to ISPs - a solution which also removes concerns about the academic appropriateness of activities carried out on the Internet. A number of results from the survey are surprising, however. The rapidity in making Internet access universally available in the laboratories, the speed at which multimedia is being supported is perhaps surprising given constrained budgets.

Abstract. We present a work in progress report of what may become our interdisciplinary-based standard for the construction of Computer Based Education (CBE) software within our Virtual University project [Tames 96] [Espinosa 95a]. Given our fast-paced workstyle, it becomes hard, if not impossible, to negotiate continuous, long lasting design meetings with several experts. These experts are faculty from diverse schools in our campus who contribute to the virtualization of a course [Espinosa 95b]. It has been proposed that the Internet become, using *Collaboratories* [Kouzes 96], a preferred means for bringing together people in situations similar to those experienced by our experts and ourselves. We suggest a theoretically sustained, but validated method for achieving a virtual cooperation using proprietary Internet-based Collaboratory software. These guildelines will allow us to reach more realistic [pedagogic and socially accepted] results in our project.

1. Introduction

We actually are in the third year of a project which aims at what we call the "Virtualization of the University" [Tames 96] [Espinosa 95a]. It includes the construction, and validation, of a series of educational software products. These are being tested at the high school and college levels. In it, the following premises hold :

1. The student must be trained to learn in an autonomous manner, developing analysis, synthesis, and evaluation skills, as well as :
2. Promoting a strong responsibility with respect to his/her learning process. [ITESM 96].

Firstly, we pretend that the current educational model used by ITESM stop being a "teaching-learning" one, that is, one in which the centerpeice is characterized by the instructor's teaching (ie. lecture) strategy, or *Teacher Model* [Boy 96], and the transfer of knowledge to the student. The new model emphasizes "learning". It is centered on the intentions of the student, his/her experience, and the involved metacognitive strategies [Nelson 92] [Morris 94] [Reeves 94].

Following this new model means that we will delegate onto the student the responsibility to administer his/her own learning scheme. This means that the resources he/she will need throughout the process are given, but will be accessed on demand as required based on a personal estimation. The instructor(s) will not interfere in these decisions.

It is our responsibility as educators, therefore, to facilitate the working (ie. Learning) materials in as many different ways as possible.

2. New Educational Paradigms

Adhering to this epistemological paradigm, a *Constructivist* [Reeves 94] one, has a series of social, cultural and pedagogical implications, besides computational ones :

1. The current educational focus is centered upon the *Instructivist* epistemological model [Reeves 94].
2. The development of computer software that conforms to the new epistemological model requires the concurrent introduction of validation and correctness criteria different to those traditionally applied by Software Engineering standards [Sommerville 92], and
3. Neither it is sufficient to reproduce the current educational materials *per se* using multimedia, hypermedia or virtual reality.

With respect to the first point, nowadays we shelter in the Instructivist epistemological model, which emphasizes the importance of goals and objectives derived from a domain where an expert dictates what is true and what isn't within the application. Such goals and objectives are categorized and hierarchically placed such that a linear model of progressive lower level to higher level steps is achieved. In our research, we tend to modify our educational schemes, trying to place them in an *intermediate state* between Instructivism and Constructivism. We attempt to provide a subjective construction of reality by a particular human being as he/she gathers experiences, does some processing on them, and incorporates metacognitive reflections to these results. No longer does the expert provide a complete truth about the real world. Our software designs take this into account.

We have just mentioned the word *metacognitive*. Therefore, with respect to the second point, the social impact this type of software designs have depend, to a great extent, on the psycosocial acceptance or rejection the [academic] community will feedback, as human validation parameters are taken into account [Reeves 94] [Morris 94]. Such parameters are extracted from the field of Cognition, and will be described later.

We now reach the third point. It is not possible to assume that we will succeed in the validation effort just by making use of the state of the art in distributed computing, such as the Java Technology [Espinosa 96d].

3. Teams again ?

The previous discussion leads us to make an attempt at reinforcing our teamwork capabilities. It is not enough anymore for the academy to work on educational virtuality on its own. We now propose collaborative work by the experts with people from support areas, such as a Virtual University Department [Vallejo 97]. In most cases, this implies a divergence from the independent work the academy traditionally performs. It is our job to promote such a collaboration. This is hard to operate in reality, however. One reason lies in a very tight schedule everyone faces, combined with long distances to be traversed. Daily operation dominates over design activities. The administration of a virtual university requires a reengineering as well, as has been reported in [Press 94] [Peters 94] and [Tames 96]. Whether teamwork can be achieved depends in these parameters as well.

4. Collaboratories at ITESM : Method

Our chances for a *synchronous cooperation* [Kouzes 96] are therefore null from a practical standpoint. We propose, as a possible solution, an *asynchronous, or Collaboratory cooperation scheme* [Kouzes 96]. The collaboratory solution implies a virtual laboratory that allows its users to access the tools, data and other resources they would normally use in a live session. In our case, such resources are determined by a *methodology for the design of educative software* within the context of the Virtual University project at ITESM.

The methodology is conceptual, but contained in practice within a Collaboratory that all participant professors and support staff are able to use. The technique consists on introducing diverse learning strategies as a particular Computer-Based Instruction (CBI) package is analyzed and designed. What strategy is used depends on the type of knowledge to be characterized. They are reported in [Morris 94]:

- Learning by doing.
- Expert Modelling.
- Situational Cognition (anchored Instruction).
- Induction.
- Drill & Practice.
- Deduction.
- Instruction Direct.

As can be observed, these practices contemplate a wide range of choices, previously defined as *Cognitive parameters*, and can be derived from both the Constructivist and the Instructivist paradigms. The reasons for choosing this particular set of strategies are :

1. Given the current institutional policies [ITESM 96], we must comply with a fixed set of academic requisites that structure our teaching work. These policies are mostly Instructivist.
2. We have concluded that a careful transition must be crafted when changing the "teaching-learning" paradigm to the "learning" one [Tames 96]. This is mainly due to the fact that our students have been trained under an Instructivist environment for many years.

5. Instructional Design Method

The methodology, taken from [Romiszowski 91] is now outlined :

1. Perform Goal specification.
2. Perform Task Analysis.
3. Perform Analysis of the Expected Audience.
4. Select an Instructional Strategy.
5. Design Content.
6. Perform Evaluation (ie. validation).

The model is analogous to the traditional Software Life Cycle as defined by the Software Engineering [Sommerville 92], and denotes the intersection of the following areas of knowledge :

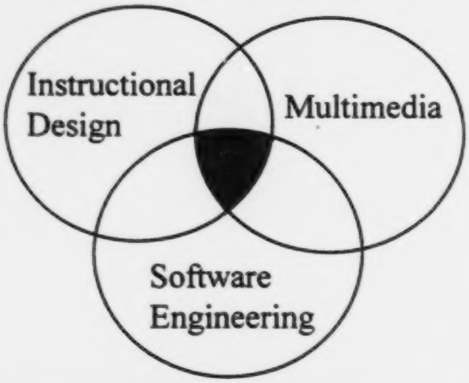

Figure 1: Multidisciplinary intersection

We now proceed to detail how a portion of this method can be ported to an Educational (and distributed) CASE tool we call a Collaboratory. The tool is derived, in part, from the EMI Model reported in [Espinosa 96b], and is being considered as a starting point for a future complete CASE tool that contains all the steps in the methodology. We actually use the method in a semi-automatic fashion in our project [Tames 96].

6. Implementation

Steps 2, 4 and 5 of the method outlined above are being reported as an implementation. We have developed a series of Web pages that function as a virtual notebook in which data is fed so that an Educational Flowchart (EF) is built. An EF is a hierarchical structure containing the models of topics and subtopics that make up a course. It specifies their direct and indirect relationships. From the standpoint of Information Systems, it is a Tree, or possibly a Graph, structure.

As the main structure of the EF is built, the nodes that compose it are filled out with data. Such data is defined from the pedagogical point of view, and is made up of *entities*. Each of these *entities* is analyzed and designed using an Object Oriented Software Engineering Methodology. We thus combine Information Systems with Pedagogy (refer to Figure 1). The justification for performing such an analysis and design relies on the fact that the resulting implementation project will be object oriented. We will deepen on this Object Oriented technique in section 10.

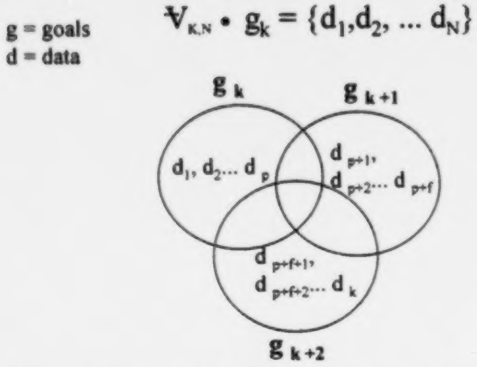
7. Instructivist Entities

We now proceed to formalize the method. Let *g* be the set of goals to be fullfilled by the educational software. Let *d* be the set of data items the professor has defined as educational elements to rely on. The Instructivist paradigm as defined before, consists on a series of predefined goals and objectives. We thus represent these sets in Figure 2 as fixed. We may therefore state that Instructivist entities are fixed.

8. Constructivist Entities

As before, let *g* be the set of goals to be fullfilled by the educational software. Let *d* be the set of data items the professor has defined as educational elements to rely on. The Constructivist paradigm as defined before, consists on a series of undefined goals and objectives. The data items are contained in a catalog-style container, and will be placed on sets in real-time. We thus represent these sets in Figure 3 as non-fixed. We may therefore state that Instructivist entities are non-fixed.

We wish to empasize that each goal may constitute one node of the EF previously described. As a consequence, the network of nodes depicts an educational relationship of goals & data.



g = goals
d = data
$\forall_{K,N} \bullet g_k = \{d_1, d_2, \dots d_N\}$

d_1
d_2
d_3
d_N
g_1
g_2

Figure 3: Constructivist method definition

9. Entity Sequencing

In order for the designer to be able to define a sequence in which the entities are to appear, we provide yet another Software Engineering construct, called *Preconditions* and *Postconditions*. Namely, a *Precondition* is the set of requisites that must be fullfilled in order for an action (ie. entity) to execute. A *Postcondition*, on the other hand, is a set of requirements assumed to be valid after the action has been executed. Figure 4 adds Preconditions and Postconditions to our scheme. The use of these gadgets allows us to relate more than one entity to others. That is, we may reuse entities as needed. We will further explain this concept later on.

10. Object analysis & design of Entities

As said before, this prospective CASE tool will aid in the development of an object oriented web page. The entities are therefore defined in terms of a class hierarchy, as shown in Figure 5.

Figure 7: Step 2 of the design

The third step is to define a pedagogical strategy (from the list in section 4). See Figure 8.

At this point, the user interface aids the user with respect to the strategy just selected. The system will not provide any further (ie. intelligent) help.

At a later (ie, asynchronous) time, the current design, stored in the WWW, will be examined by some other member(s) of the team, and feedback will be emitted. This is shown in Figure 9, as the changed are reported by this other user.

Finally, someone may propose two other strategies aimed at understanding what a Bus is. These need not be complementary (ie. reinforcing one another). There may be other ways in which a student may learn. The original model is thus enriched with the participation of several experts. See Figure 10.

The reader may already have noticed that the graph (or tree) representation of the educational design (EF) is updated to the right of the detailed model. This is the operational scheme used by our Web Page. Condensed results (ie. statistics) are presented to the user in the form of reports and summaries, which allow the quick view of data which is not usually understandable to all types of users.

11. Experimentation

As cited in [Kouzes 96], the software is to be socially accepted for it to trascend. We will be conducting a series of important experiments. These are crucial if we are to obtain a stable and long lasting product. This software is designed based on educational criteria, and validated as reported in [Espinosa 96a] and [Tames 96]. The implementation is written in Java, and makes heavy use of database access and remote message passing.

12. Conclusions

We have obtained an initial method for the development of educational software by integrating instructional design, multimedia and Software Engineering, based on an educational background that resembles our institutional needs as closely as possible. We want to emphasize how important it is to bring together a team with these multidisciplinary characteristics. As we maintain this line of research, we will [eventually] achieve a definition of what bringing a course to a virtual state really means.

Strategies for Developing Cost-Effective And Powerful Interactive Multimedia Educational Materials

Dr. Peter Evans
Distance Education Centre
University of Southern Queensland
Toowoomba Queensland 4350
email: evansp@usq.edu.au http://www.usq.edu.au/users/evansp/

Abstract: Interactive multimedia (IMM) will only become a mainstream educational method if IMM titles:

- result in excellent educational outcomes (at least better than other methods); and
- can be developed within reasonable resource constraints.

Without achieving both of goals, IMM will be relegated to the margins of educational materials development and even brilliant projects will burn brightly for a short time before sinking below the surface without a trace. This paper examines some strategies we are using at the University of Southern Queensland to develop affordable and powerful IMM and web delivered learning environments.

Impetus and Barriers for Multimedia Development

Most universities and other education and training providers are increasingly using flexible delivery and interactive multimedia (IMM) technologies (digital tools used to represent, process and transmit textual, graphic, audio and video information). Increased use is due to the changing nature of students and a need to provide educational products marketable to a range of people at a time, place and pace defined by the user.

However, IMM materials require longer and more complex developmental processes involving many different groups of people working together. Also, if IMM systems are qualitatively different to traditional educational media (paper, video, audio) then academics must totally rethink the educational process. Ironically the speed of technology development can also be a barrier to the development of IMM. For example, the **technoluster** who is forever, trying beta releases and has a hard disk full of software which is not actually used for any **real** task. In a world of almost unlimited possibilities enabled by technology, it is important to carefully identify what we want to do and then work towards achieving this.

While these problems apply in all contexts some occur more often in universities. "Paralysis through analysis" often afflicts academics who endlessly debate the "perfect" way of doing something and end up doing nothing. Academics are also notoriously loathe to use a resource which they themselves have not developed.

Strategies for Affordable IMM Development and Use

The remainder of this paper examine strategies to decrease the development and delivery cost of powerful IMM titles. Some strategies may be implemented at the institutional level, while others are more applicable at the levels of the IMM development group or the individual project team. This paper does not attempt to quantify, in absolute terms, development and delivery costs. Many of the strategies discussed in this paper are based on the ratio between development time and the time the package is used. Thus, either increasing the number of users, the time the package is used, or spreading developmental overheads over a number of projects will result in lower per unit developmental costs.

Focus on Core Objectives

IMM technologies are impacting on all university activities—teaching and learning, research, administration and community service. Within teaching and learning, IMM may be used in several different ways emphasising different aspects of the teaching-learning episode and different educational models, e.g.:

- Computer Assisted Learning (CAL) focusing on presentation of carefully structured teaching sequences;
- Computer Managed Learning (CML) focusing on assessing learning and managing access to materials;
- Computer Mediated Communication (CMC) focusing on interactions between people;
- Interactive Multimedia learning resources focusing on finger tip access to educational resources.

While, features of these applications are converging it is critical that IMM development groups focus on one or two styles in order to develop affordable products. At USQ we are focusing on the development of IMM learning resources for several reasons. IMM learning resources may be used in a number of units and are generally used for significant amounts of time compared to traditional CAL materials. The flexible structure of IMM learning resources also allows the inclusion of CAL, CML and CMC facets when appropriate to the needs of the users, the tasks at hand and the features of the content.

A further advantage of focusing on IMM learning resources is that it allows us to capitalise on the vast amounts of print based information which most universities already own. I am not suggesting that existing paper based content be simply reformatted for screen presentation (shovelware), but rather that this information should be integrated into the IMM environment in a way which adds value for the user. For example, a current USQ project involves a CD-ROM based database of images and animations. While the majority of students will read the text of the unit on paper, this text will be also included on the CD-ROM, allowing the student to more easily find, understand and use the media resources.

Theories from psychology, education, information science and human-computer interaction can also be used to focus the implementation of individual projects. Without such guidelines it is difficult to focus on clear goals and the plethora of possibilities offered by IMM is one way of overspending development budgets. One such principle is that the IMM environments should reduce the cost for a person to find, understand and use a piece of information, as well as increase the value of that information. However, the value of an IMM environment depends on a complex set of interactions between the features of the content, the users, the tasks they are set, and the tools that are provided [Evans 93].

Collaborative Work Between People and Groups

IMM development requires co-operative input from people with different expertise (content, video, graphic, textual, programming, project management, legal etc) and from different departments. If a university is to develop useful IMM, then it is necessary to foster a strong coalition between these different groups. Strategies which offer individuals and groups opportunities to best utilise their strengths and participate in a "win-win" collaborative effort, are more likely to be effective then "brute force" strategies (e.g. restructuring).

Within USQ both top-down and bottom-up strategies are used to foster cross-sector collaborative groups. The Flexible Delivery Committee [USQ 95] consisting primarily of Deans and the Deputy VC sets policy and broad parameters for the direction and pace of the use of Flexible Delivery technologies. The "multimedia@USQ" [Multimedia 96] user group supports practitioners who are using IMM and provides a forum to showcase their work, and share experiences and expertise. Collaborative work is also fostered at the level of the unit team which at USQ consists of content experts, an instructional designer and if required an IMM developer.

Strategic Planning and Staged Development

Deployment of IMM educational materials requires faculties and the university as a whole to set long term plans if costly mistakes and delays are to be avoided. Long lead-times are also necessary to ensure that the infrastructure is available for the IMM to be effectively delivered to students. Many faculties within USQ are currently moving towards requiring students to have access to a certain level of computer at a specified time in the future. This means that core educational materials may be distributed electronically without the added cost of a dual development and delivery system. In return for their investment in computers, students will be assured that they will use the computer in the majority of units over the duration of their course. Each USQ faculty has prepared a rolling 3 year plan for the introduction of flexible delivery technologies.

Deliverable Products vs. Ongoing Expertise and Infrastructure

Another way of reducing developmental costs is to ensure that each IMM project is conceptualised as both a deliverable product **and** also as an opportunity to develop infrastructure, expertise and models which will be used in future projects. The mix between these aspects is different for each project and it is important not to overly force the aspirations of individual projects into the "grand plan" for the group. While most projects broadly support this developmental principle, each is periodically examined to ensure that it is contributing to the expertise and skills of the group. The "retained" part of each project may take several forms.

Content structuring and markup: A major asset of any university is the intellectual property of its staff and its expression in teaching materials. While paper based content will be used into the future, it is clear that this content should be organised allowing it to be moved from one presentation format to another-"author once--play anywhere". For example, the one source document could be used as the basis for documents distributed on paper, CD-ROM or perhaps the WWW. Markup languages such as SGML are becoming increasingly common ways of "future proofing" content.

Functional tools and interfaces: Projects in different faculties will emphasise different tool sets and different representational media e.g., calculators and scientific simulations would be more common in a unit taught in the Faculty of Engineering and Surveying than an Art or Education unit. However, there is also a core of functionality and media types which are consistent across all disciplines. For example, all IMM learning resources should allow the user to follow thematic links between information. It is imperative from a cost effectiveness point of view to ensure that the tools used to create these links, the underlying data structures, and the way in which students use them are developed once to avoid "reinventing the wheel". Tools such as context sensitive online help, word search and indexes should also be reusable in a variety of titles. A complete functional specification of the Hathaway CD-ROM can be found in Hathaway [Evans 96].

Underlying code: While true cross-platform development and delivery is still problematic, developmental costs can be reduced significantly by implementing functionality in ways that are robust, generalisable and maintainable. The code should also be written in a way which isolates key functionality from the underlying hardware and software. For example, tools are being produced that facilitate translation of content between systems such as HyperCard, SuperCard, TookBook and Director.

Project Management

IMM projects, like other projects involving many people, benefit from close project management in which roles, responsibilities, and demonstrable mile-stones are clearly specified. This does not mean that all members must attend long minutely minuted meetings. Generally project goals are not achieved in meetings—the meeting establishes the potential to achieve goals but the goals are achieved through work in between the meetings. We have found it useful to have short weekly meetings after which actions and decisions are minuted and attached to a single name for action.

Development Processes

Software Platforms

Numerous authoring systems claim to increase the productivity of multimedia programmers--some even claim to replace the programmer. All environments have strengths and weaknesses and this paper is not the place for a platform war in favour of a particular environment. However, it is important to carefully match the skills of the programmer with the design specification of the project and the features of the tools which are used. For example, the Hathaway CD-ROM was developed using a general purpose scripting language because it allowed us the freedom to create the tools which were required.

Development Tools

The development of the Hathaway CD-ROM involved creating numerous tools which will be used in future projects. For example, link creation involves selecting the start anchor (a phrase of text, a visible button or a region) and then selecting the end anchor. The link is then automatically created, stored in the link database and the anchors visually highlighted. Once created links can be verified, sorted, or processed using other tools.

Hand-coded "button" Multimedia vs "tool" Multimedia

Some multimedia products are entirely hand-coded and all functionality has been created on a "one-off" basis. Often these products are created by content experts who have recently been visited by someone selling the "ultimate" authoring tool. This process is not only very labour intensive during its creation but also almost impossible to maintain. This is a common reason why initial breathless enthusiasm is often replaced by the sobering realisation of the limits on the depth or amount of information many IMM environments contain.

In contrast, the goal of the developer should be to create IMM titles which provide tools for both the developer and the end-user. For example, attaching several index terms to each node and providing a flexible way to navigate these index terms provides the user with an opportunity to investigate thematic issues which might not have been considered by the developer. Moreover, the value of these index terms increases with the number of nodes rather than collapsing under their own weight as they may do in a hand crafted system.

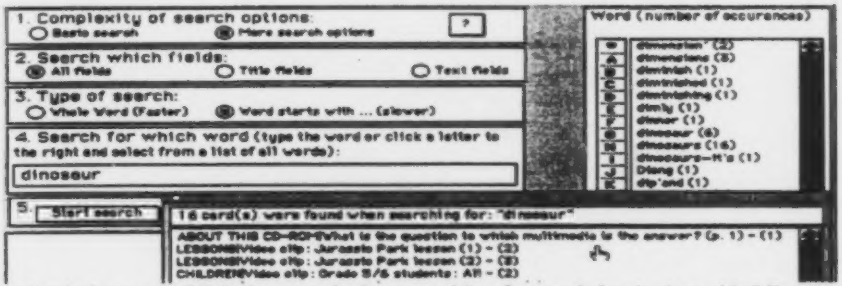
Rapid Prototyping

Some models break the software development process into a sequence of steps such as requirements analysis, specification, implementation and testing. In my experience such models have not been very useful in IMM development, partially because people and the project are in a continual state of evolution and development. A more useful approach has been rapid prototyping in which a prototype (either a sketch on paper or a computer implementation) of a small part of the project is constructed and then placed "on the table" for examination by the project group.

Tools for the User

The Hathaway CD-ROM contains tools to help the user to navigate, find information, understand information, and use information. These are general purpose tools which have been used in subsequent projects.

Tools for Finding Information



1. Complexity of search options:
○ Basic search ● More search options

2. Search which fields:
● All fields ○ Title fields ○ Text fields

3. Type of search:
○ Whole Word (Faster) ● Word starts with ... (slower)

4. Search for which word (type the word or click a letter to the right and select from a list of all words):
dinosaur

Word (number of occurences)
dimension' (2)
dimensions (8)
diminish (1)
diminished (1)
diminishing (1)
dimly (1)
dinner (1)
dinosaur (6)
dinosaurs (16)
dinosaurs—it's (1)
Diang (1)
dip'and (1)

16 card(s) were found when searching for: "dinosaur"
ABOUT THIS CD-ROM\What is the question to which multimedia is the answer? (p. 1) - (1)
LESSONS\Video clip: Jurassic Park lesson (1) - (2)
LESSONS\Video clip: Jurassic Park lesson (2) - (8)
CHILDREN\Video clip: Grade 5/6 students: All - (2)

Figure 1: Search window and of "hits" returned when searching for words beginning with "dinosaur".

Broadly speaking electronic environments provide two different styles of tools for people to find information—query based searching and browsing. The Hathaway CD-ROM provides both methods and allows the user to select the one that is most relevant to them and the task at hand. Figure 1 shows the "Query based Word search" window [Fig. 1] allowing the user either to enter a search term or select it from a list and which returns a list of all nodes containing that term. While indexing the database is very slow (over 8 hours on a mid range PowerPC

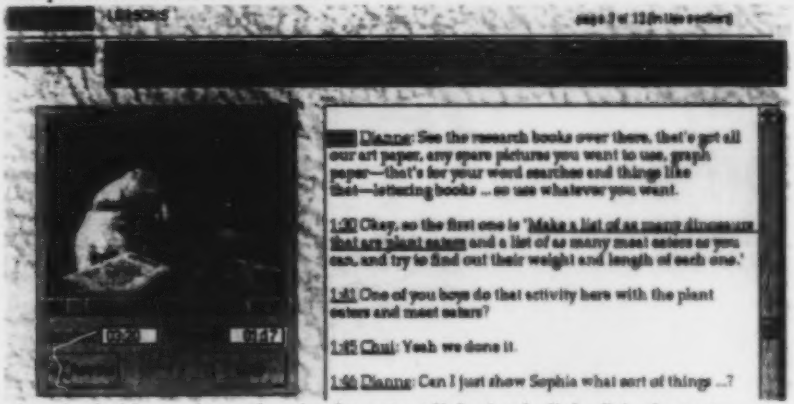
BEST COPY AVAILABLE

based machine) retrieval is very fast (less than 10 seconds for most searches). The effort involved in writing this indexing and retrieval tool is justified through multiple reuse.

Tools for Recognising and Understanding Information

Once information is displayed, the user has to understand it and recognise its relevance before it can be used. Electronic environments can provide many tools for helping the user to understand information including:

- using multiple interlinked representations of information;
- highlighting relevant parts of the data;
- providing links to related information; and
- providing interpretations of the information.



Dianne: See the research books over there, that's got all our art paper, any spare pictures you want to use, graph paper—that's for your word searches and things like that—lettering books ... so use whatever you want.

1:30 Okay, so the first one is 'Make a list of as many dinosaurs that are plant eaters and a list of as many meat eaters as you can, and try to find out their weight and length of each one.'

1:41 One of you boys do that activity here with the plant eaters and meat eaters?

1:45 Chui: Yeah we done it.

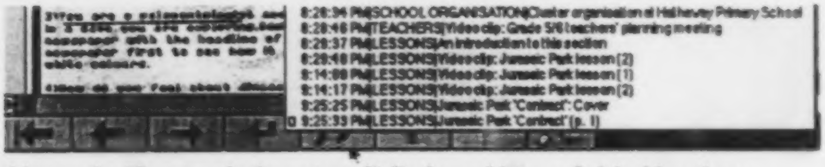
1:46 Dianne: Can I just show Sophia what sort of things ...?

Figure 2: Synchronised video and text showing hypertext links (underlinked) in the text.

The Hathaway CD-ROM provides all of these tools and presents information using a range of interlinked symbol systems (text, images, video and sound). For example, the video based interviews are linked to a synchronised text transcript. The synchronised nature of the text and video means that students can browse through either to find the corresponding part of the other. Additionally it means that we were able to use tools traditionally applied to text to also work with video and other time based media (e.g. animations moving around a school building). For example, we can create hypertext links between specific segments of video or use word search to search for any video were a particular person is speaking. Figure 2 shows a segment of video of a lesson where the teacher is guiding a student through a worksheet. Links in the text allow the user to synchronise the video [Fig. 2], see glossary entries for the speakers or follow hypertext links (clicking on "Make a list ..." displays a scanned image of the worksheet on the desk) to related information.

Because we have developed general tools to enable this synchronisation of text and time based media to be easily created we are able implement this at numerous places in the package at little cost.

Tools for Collecting, Using and Understanding information



8:20:34 PM|SCHOOL ORGANISATION|Cluster organisation at Hathaway Primary School

9:25:33 PM|LESSONS|Jurassic Park 'Contract' (p. 1)

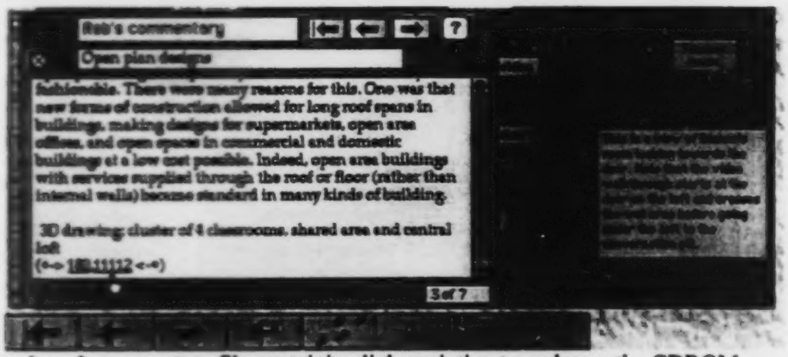
Figure 3: Clicking on the "footsteps in the wet sand" displays a history of visited locations.

If hypermedia technologies are powerful tools for presenting and organising information then **end-users as well as developers** must have access to tools that enable them to use, link, and organise relevant information. General purpose tools for collecting information in the Hathaway CD-ROM include automatic histories, annotated

BEST COPY AVAILABLE

bookmarks, and research notes. Figure 3 shows a list of nodes which have been visited in the current session allowing the user to return to a recent location by selecting it from the pop-up menu [Fig. 3].

Users of the Hathaway CD-ROM can create links and record notes in commentary file stored on their own floppy or hard disk. Figure 4 shows such a commentary file and commentaries will also be used to submit assignments either via floppy disk or email [Fig. 4]. When an embedded link (shown as the underlined number) is clicked the appropriate part of the case record is displayed and the students interpretations could be verified by looking at the surrounding information.



fashionable. There were many reasons for this. One was that new forms of construction allowed for long roof spans in buildings, making designs for supermarkets, open area offices, and open spaces in commercial and domestic buildings at a low cost possible. Indeed, open area buildings with services supplied through the roof or floor (rather than internal walls) became standard in many kinds of building.

Figure 4: Floppy based commentary file containing links pointing to nodes on the CDROM.

Summary

While the power of a multimedia title it not necessarily directly proportional to the cost of its development, the process of multimedia development is a continual process of balancing cost and power. If products are not powerful and thus don't justify their existence, then the use of IMM for university teaching and research will be significantly slowed. On the other hand, even the most brilliant IMM project will not be successful in the longer term if it can't be developed within a reasonable budget.

Asynchronicity: Distributed Learning Communities

Kevin C. Facemyer, Ph. D.
Director of Virtual Washington State University,
Office of the Provost,
Washington State University
KCFacemyer@wsu.edu

Abstract: This paper explores the new roles of learners and universities as we, or others, shift from teacher-centered instructional formats to learner-centered instructional formats. The first section, entitled *Historic View*, describes how much of what is done in universities qualifies as an asynchronous model of education and how this shift to asynchrony could be more complete and deliberate. The second section, *Future View*, describes how universities may change their orientation to the methods of instruction away from teacher-centered formats to learner-centered formats. The final section, *CyberStoa*™ offers a criterion for judging technologies' optimum role in fostering distributed learning communities. This paper offers a set of reflections and starting points on which to analyze our initial efforts at shifting toward asynchronous learning networks as a more prominent mode of Higher Education.

Historic View

Traditionally, college and university faculty and students have convened in classrooms for the expressed purpose of teaching and learning. This scenario is so prevalent and assumed that stating it sounds like hyperbole. We all know what Higher Education looks like; a professoriate lectures to a large mass of attentive studentia. We also know that the profesoriate and the studentia are brought together into the same large lecture halls under the guise of learning. However, deep within this scenario several expectations and assumptions exist. Several of these assumptions, when closely examined are if not obviously false at least questionable.

Traditional views of teaching allow teachers several active roles: lecturing, offering explanations, describing lab activities, setting out exercises, guiding practice sessions, conducting evaluation and assessment, guiding critical discussions as well as many others. Traditional views of learning offers learners relatively few roles, most of which are passive: listening, note taking, following instructions, practicing skills, or performing memory tasks during evaluation. Over the last few years research in the cognitive sciences [Kandel & Hawkins 1992], [Fishback 1992] and empirical observation of learning situations [Nunn 1996], [Goodlad 1995], and [Cuban 1986] has lead educators to conclude that these predominantly passive roles of learners have, in fact, inhibited learning or relegated it to occurring during out-of-class time.

Reading about topics heard in lecture, practicing skills described or demonstrated, discussion with other learners, writing up reports, analysis of data are all typical tasks and activities that students have completed in order to learn. Often these are done out of class. There is nothing unusual about this or the expectation that much of a course's cognitive activities happen out of the classroom. This is important for several reasons; two are worth describing in detail.

First, this opportunity or expectation, for learners to process, practice, discuss, read, write, diagram, hum , dance, plot, diagram, investigate or classify allows them the freedom to explore the intellectual demands of the specific learning situation in manners comfortable or efficient to the learner. Whether one subscribes to Gardner's Multiple Intelligences, [Gardner 1993] or learning styles, or to a culture-specific/background-specific orientation to learning in its various forms, it is a rare individual or theory that allows for only one single path to learning. This traditional asynchronicity, the expectation that students will on their own time work through course material in their own ways, has allowed, but not fostered multiple orientations or paths to learning.

Second, this opportunity or expectation, allows learners to gain contrast, alternate sources, explore concepts in new ways, in a location amenable to the learner. While students are tied to campuses where lectures or specialized laboratory equipment is located, they are expected to learn beyond the lecture hall or laboratory. At home in soft light, at work while doing labor, while driving, while exercising, at night in dreams, good learning takes place; learners are not expected to do all of their learning in the classroom. This traditional asynchronicity and the expectation, that students will learn in setting of their own choice, has allowed limited geographic dispersion of learners due to the ties of the lecture hall.

With this historic description of education it is clear that many educators facilitate asynchronous learning. There are other ways that learning is asynchronous. In any classroom of learners there are many different paces, patterns and paths to learning any subject or skill. Within these individual learners there are also a limited number of "sublearnings" that can happen in many different orders. Generally, the class is in the same realm on the syllabus and many learnings have precedent and antecedent sublearnings, but to a large extent, learning is clearly a process that in not tightly synchronized to teaching. Therefore, building on traditional views of learning and education, describing what asynchronous learning is and what its benefits are should not be difficult. However, proving it efficacious, might be difficult if not impossible, based on the complexities and difficulties associated with educational research.

So far, we have explored and might agree that . . .
- In traditional classrooms, learning is not synchronized with teaching.
- In a group of learners, learning is asynchronous.
- In any individual there are many asynchronous elements to learning.

Future View

For the purposes of this discussion the designation "asynchronous learning" implies that the acts of learning and the acts of teaching are not simultaneous or colocal. Here I describe in two steps, what shifts toward asynchronous learning might look like (Desynchronization) and then how the shift might be coordinated (Coordinating Desynchronization) and assessed.

Desynchronization. Aside from the above described asynchronous learning activities, adding just a few new elements liberates, but does not exclude learners, from the colocal expectations of lectures and in some cases, laboratory experiences. The elements of asynchronous learning are not aimed at separating students from instructional aid or from each other, in fact quite the opposite is true. There are several types of activity that are predicated on groups of students interacting (group discussions, team mastery of skills, . . .) and student/teacher interaction (remediation, feedback, mentoring . . .).

Decreasing the dependence of instruction on lecture and shifting to asynchronous techniques could take several forms, ranging from simple and elementary to advanced and complex; these are just a few quick examples:
- replacing lectures with video taped presentations, or with Internet based multimedia presentations, thus allowing participants to view presentations multiply, at their pace, and at their personally optimum times,

- replacing the administrative elements of classtime (passing out papers, handling attendance, addressing questions personally, . . .) with Internet based document distribution or asynchronous bulletin board question-and-answer postings,
- replacing limited laboratory experiences with Internet based interactive multimedia environments capturing the elements of these learning scenarios with the added convenience of Internet transportability and speed and ease of data collection,
- implementing coordinated, credited and endorsed small group meetings for discussions that can not be moderated well in large lecture formats,
- implementing coordinated, credited and endorsed work sessions connected with specific skill or task outcomes, and
- implementing coordinated, credited and endorsed peer-mentoring, peer-tutoring and peer-coaching strategies are just a few of the ideas about how to convert from teacher centered instruction to learner centered instruction.

This list is incomplete and limited only by imagination. Good educators are likely to be able to produce many more methods for enhancing learning environments that, not just make possible, but endorse and credit specific types of asynchronous learner-centered learning activities. This list is designed to be illustrative of the shift to asynchronous learning environments. The last three examples emphasize the importance of peer and student/instructor communications networks. As this shift to asynchronous techniques occurs a concordant shift in assessment strategies may also take place.

This shift towards asynchrony should be evidenced by changes in assessment and evaluation strategies from the standard single-purpose model to the individual purpose model. If this learning is conducted by multiple paths and for multiple purposes, the assessment should reflect this. This shift should be evidenced by more "authentic" assessment and by more social opportunities for understanding the results as feedback in more formative settings. As the shift from summative to formative assessments occurs, the tendency to view outcomes as fixed, rather than negotiated, will tend to disappear, and learning paths will converge on success rather than be truncated at the termination of the contracted course engagement. As these trends occur, or to the extent that they do not occur, there are organizational opportunities and impacts possible.

Coordinating Desynchronization. The organized institutional efforts aimed at incorporating faculty's use of asynchronous learning networks are directed toward shifting the culture form a Teaching Paradigm change to a Learning Paradigm [Barr & Tagg, 1995]. Barr and Tagg (1995, p 18) cite Peter Senge's *The Fifth Discipline* [Senge 1990], in support of organizational changes to reflect the shift in values. To Barr and Tagg (and Senge), changes to the organization supporting the learning paradigm are as important as the decision or desire to shift towards the learning paradigm. In other words, a good metric of the university's efforts to shift its commitment towards learner centered instruction would be a description of its organizational change or development. In a generic way this means that organizations committed to shifting toward asynchronous learning networks will have new organizational features addressing these aims, or old organizational elements will be repurposed toward these new goals. In organizations that have no detectable organizational adjustments, will despite their rhetoric, have no real shift in effort toward the learner centered goals of asynchronous learning. A simple set of coordinated organizational activities targeted toward technological facility and social support, should occurr by or focus on asynchronous learning networks as the common vehicle for organizational change and student instruction. Universities sensitive to preparing students to be self-directed collaborative learners will undoubtedly focus on asynchronous learning networks as a key element of their student preparation and their oprganizations will cahnge in relation to their committment. If not other credentialing agencies will arise to fill a consumer desire to credit learning experiences outside of classrooms, which in all probability will utilize asynchronous learning networks. Several university scholars have explored this issue [Langenberg 1966] , [Casper 1995], and [Wulf 1995] and many agree that these forces will impact higher education and that one of their probable modes of operations will indeed be distributed asynchronous learning networks.

CyberStoa™

As the technology plays a larger and larger role in uniting students with learning experiences, technologies' role becomes more and more critical. Mechanical features of reception, speed, ease, manageability, intimacy and a host of other hygiene factors will be very important to the success of learners in distributed telecomputing-dependent learning situations. Organizations that attend these issues in both design and delivery phases will emerge as the quality leaders in this field. Institutions expecting high throughputs, yet with low quality may not be able to stay in business in an arena where the competitors are global and absolutely no geographic barriers exist for course delivery and participation. In instances where there is less and less institutional affiliation such as brand recognition or attending universities of popular football teams, the educational and technological environments will be more direct issues in choosing educational settings. Attendance will no longer be based on tradition and extracurriculars, the institutional quality may become to be solely judged by the technological faces and interfaces for learning.

So what criterion would be optimal in terms of evaluating the technological aspects of organizations and their delivery mechanisms? I offer one: transparency. Transparency that translates into ease of use, lack of distracters, clarity of purpose and function, minimized administrivia, simplicity in operation all will be features of successful technological environments for learning. In the same way that learning works best in well light, quiet rooms, with little cognitive distraction, the technological environments that allow us to interact in clean, efficient, unencumbered fashions will be both preferred and more successful.

Currently there are several asynchronous tools for communication, simulation and interaction with a variety of multimedia. Successful systems will have the standard benchmarks of transparent utility and function that devices such as the telephone and the water fountain have. Without directions is their use transparent? Does the medium disappear? Is the experience of extracting the message or the water more distracting than necessary? Is the placement central to purposes? Do the uses match the purposes? Or are placement and uses contrived? This simple benchmark seems to support most of the critical use issues associated with technology. Negroponte (1995) describes the interface as one of the most important issues in computing and technology and describes the best interface solutions as "intuitive." Without delving into common experience and intuition, the touchstone of transparency seems to fit as a useful criterion of technology placement and use.

Test this criterion on your use of other technologies. Does the programming of your VCR obscure your viewing movies? Does adjusting the various settings in your automobile preoccupy you and distract you from driving? Does your computer interfere with your work? With these types of comparisons and judgments, then apply this criterion to a hypothetical learning situation; does the delivery mechanism interfere with your learning? Does the involvement in groupwork in a distributed setting hamper your learning? Does the dialogue established between students flow, unimpeded by technology? Are the channels of delivery unencumbered by bandwidth, velocity, or needless user protocols? At times when data flow velocity is critical are the chosen modes capable? The use of the transparency criterion can be summarized: As a learner is your primary experience in a technologically assisted asynchronous learning network involved with learning or with technology?

Consider the stoas in ancient Greece. These were little more than covered pavilions or walkways. They were halls in which scholars could roam and discuss issues and ideas. They were open to the air and the public, and they had no walls. Imagine these elements of structure applied to technology. Does it pose barriers? Does it close off or partition learning into boxes and rooms? Asynchronous learning in technologically supported distributed communities would resemble CyberStoa™ in their ease of use, openness and simplicity. This simplicity and ease of use are targets of successful VWSU activities.

Conclusion

This paper briefly described the elements of asynchronous learning which often already exist on the university campus and then proceeds to describe ways that the asynchronous environments will benefit students and future universities. This paper describes methods and systems which foster the shift toward asynchronous learning networks and their evaluation. Shifts in the functions and roles of technology were explored by describing the successful criterion of transparency and an idealized model: the CyberStoa™. To the extent that these are testable hypotheses, the conditions and expectations described within, could be the basis for research into the efficacy of telecomputing in asynchronous learning networks.

The concept of Transparency was discovered with Kristi Rennebohm-Franz in conjunction with analyzing the ease of technology use by 6-8 year olds. The concept of the CyberStoa™ as a metaphor for electronic learning was originally articulated with and by Jon and Ellen Spaulding.

IPERtool: an Authoring Visual Environment oriented to the Development of Educational Hypermedia Applications

Laura Farinetti, Aldo Ghigliano, Fabio Maino
Dip. di Automatica e Informatica
Politecnico di Torino, Torino, Italy
E-Mail: {farinetti, maino}@polito.it

Abstract: Starting from the statement that hypermedia systems are useful tools for supporting educational communication between teachers and students, in this paper we examine the requirements of an ideal hypermedia authoring tool oriented to the development of didactic products. Ease of use, production of material that is usable both in a local and in a distributed environment, compatibility with other hypertext formats and automatic, secure and reliable publishing of information are identified as the key characteristics for this purpose. After that IPERtool, a visual environment for hypertext authoring developed at Politecnico di Torino, and especially though for helping teachers with no computer science background in producing their didactic material is introduced with respect to the identified requirements. We list and comment the main characteristics of IPERtool from the author's and the user's points of view, give a technical description of the tool and finally consider a number of applications that we developed at Politecnico di Torino using IPERtool as the authoring tool.

1 Introduction

We, like other researchers in the educational field [Conklin 87] [Nielsen 90], consider hypermedia as useful tools for teaching and learning [Farinetti & Scarafiotti 1995a] [Farinetti & Scarafiotti 1995b] [Farinetti & Scarafiotti 1996]; the hypertext structure combined with the characteristics of multimedia presentation offers an emotional impact on the students, the potentiality of grabbing their attention, the redundancy of the communicated information that can strike simultaneously different sensorial inputs, and an organization of the concepts which resembles the process of knowledge building.

A teacher, then, can become the author of an hypermedia tool, that will support him in the traditional communication inside the classroom or will substitute him in case of distance learning scenarios. The motivation of the teacher in experiment this new didactic strategy is usually strong, but his unhappiness in dealing with the practical problems of the implementation can be even stronger; today the number of available commercial tools for hypertext authoring is very large, and the author usually have to choose whether to distribute the product on a telecommunication network (Internet) or to use a local support (CD-ROM).

The growing popularity of hypertexts is strictly related the increasing accessibility of the authoring process: HTML, the language for Internet publishing, is a simple language, and non-experts in computer science can learn it and produce their own pages with little effort. In many cases, however, teachers feel that this way of authoring is a waste of their time, and think that the process of writing tags and checking the result with a WWW browser (Netscape, Mosaic, Microsoft Explorer, ...) is annoying. Often the implementation process is then committed to an assistant that could have a weaker pedagogical skill, and the communication between the two authors becomes difficult and time-consuming. Some teachers, in addition, would appreciate the opportunity of having a way of distributing the same hypertext both on Internet and on a local support without having to reorganize and reprocess the material [Brown 1994].

Another feature for helping the teacher would be the possibility of importing didactic material written in a different format (document, text, Windows Help hypertext, ...) without much effort, and to export the resulting product in a different format.

The ideal authoring tool, then, should meet all these requirements, but should also have a very simple, easy to learn, easy to use interface, possibly a visual one that operates according to a WYSIWYG (What You See Is What You Get) philosophy. This is what we had in mind (i.e. our "model" of a potential teacher-author) when we designed and implemented IPERtool, a WYSIWYG environment for hypertext authoring developed at Politecnico di Torino.

IPERtool has been designed especially for teachers with no particular programming skill, and its aim is to give them a complete visual environment for writing their hypertexts and publish them both in Internet and in a MSWindows environment. The idea of designing IPERtool grew from a much less challenging need: the problem of translating an already existing hypertext written for the Windows Help into an HTML one. Since the available automatic translators were not satisfying, and since we did not want to translate it manually, we started to define the requirements of an authoring tool for writing and browsing hypertext which were completely compatible with HTML and which permit the translation among the most used hypertext formats.

In section 2 we will examine the main characteristics of IPERtool from the author's and the user's points of view, while in section 3 a technical description of the tool will be given; section 4, finally, will describe a number of applications that we developed at Politecnico di Torino using IPERtool as the authoring tool.

2 The author, the student and IPERtool

Our aim was to simplify the "relationship" between a teacher-author and his authoring tool, and to guarantee a large distribution of the educational product once it is finished; we defined a number of requirements for reaching these goals:

- authoring tool easy to use
- local browser available for the local fruition of the educational products
- fruition of the educational products in Internet
- compatibility with other hypertext formats
- automatic, reliable, secure publishing of hypertexts

We will examine these characteristics in details in the following paragraphs.

2.1 Authoring tool easy to use

The authoring system is addressed to anyone can use a Personal Computer, and who is familiar with the usual Windows interface. IPERtool follows the WYSIWYG (What You See is What You Get) philosophy, and permits the user to see immediately the layout of the page that he is composing in the same way it will appear using an Internet browser.

The IPERtool editor permits to easily change the background and the style of the fonts or to insert pictures, frames, tables, text files, image maps, always working with dialogue windows, thus reducing the effort of memorizing the names of the elements. The built-in help can guide the users when they have problems, and a simple step-by-step tutorial is provided to introduce the tool to the users.

2.2 Local fruition of the educational products

IPERtool can be used to browse hypertexts locally, without the Internet connection. Therefore also users who do not have an Internet subscription can read them, and user who have it can download the applications from the network and browse them locally. The download of a whole hypertext can be achieved in a single step: this characteristic reduces the connection time and permits the users interested in local copy of the application to get it without browsing the hypertext and saving one page at a time.

IPERtool can be distributed as a complete authoring environment, or as a read-only browser together with an application written using the authoring tool, when the aim is the distribution of a hypertext and the addresses should not be able to modify it. With one single button IPERtool allows to print the whole hypertext, a subset of pages or a number of linked pages. In the last case the user can browse the hypertext marking the interesting pages, and the next printing command will have the effect of printing only these pages.

2.3 Internet fruition of the educational products

With IPERtool we overcome the problem of adding networking capabilities to existing local hypertexts [Brown 1994] and the consequent questions about feasibility (is it easy to add networking as an afterthought to an existing hypertext system?), authorship transparency (can networking be added without authors having to change their existing hyperdocuments?) and readership transparency (can networking be added without changing the way readers use the hypertext system?).

The reason is that IPERtool is designed on purpose to produce hyperdocuments that are usable both in a local environment (Personal Computer with MSWindows) and in a networked one (Personal Computer with Internet connection and a WWW browser). Every hypertext written using IPERtool can be viewed with Netscape Navigator or similar Internet browser, and it appears indistinguishable with respect to a hypertext written in HTML. The same functionalities (tables, frames, forms...) implemented in Netscape Navigator are available, and the format of the included pictures, sounds and movies is the same. Also the hypertext keyword management is accessible using a simple built-in form-based interface.

An advantage with respect to hypertext written in HTML is that the whole hypertext is contained in a single file, and the distribution is consequently easier.

2.4 Compatibility with other hypertext formats

The compatibility with other document formats is important in the light of the reuse of information, and in many case teachers have a great deal of didactic material already prepared.

IPERtool has an internal translator which permits the inclusion of hypertexts written using the Windows Help or HTML. In these cases not only the content of the nodes is maintained, but also the structure of links and keywords. Besides that, the inclusion of ASCII text or already written Word for Windows documents is possible and immediate. Furthermore, IPERtool can export either in HTML or in RTF, choosing whether to include or not the link information. In a hypertext written with IPERtool users can include references to standard Internet URLs (for example links to external HTML pages); on the reverse, a standard HTML page can include links to a specified page into an IPERtool hypertext.

These characteristics make the integration of already structured information easy, and the reuse of already written documents and hyperdocuments immediate. A general view of IPERtool import/export capabilities is shown in Figure 1.

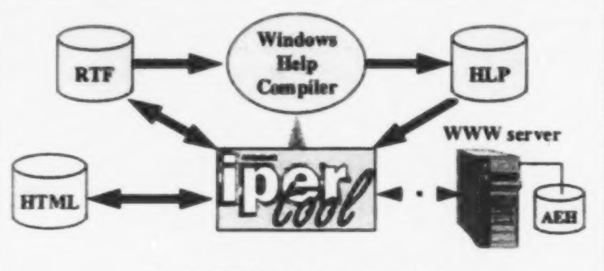

Fig. 1 - IPERtool, a general view.

2.5 Automatic, reliable, secure publishing of hypertexts

The process of publishing in Internet the hypertext written with IPERtool is completely transparent both to the author and to the Webmaster of the WWW server. Once IPERtool is correctly installed on the Internet server, the only thing the author has to do after she has finished with the hypertext is to choose an item on a menu and digit username and password; the hypertext is transferred into her home directory without the intervention of the Webmaster, and without the risk of corrupting other authors' hypertexts. User authentication is provided with a simple MD5 based challenge-response mechanism.

Trained system users or system administrators can however transfer manually the hypertext: they have to send via FTP a single file and write a simple HTML anchor to link it to an existing page.

3 IPERtool

IPERtool [Ghigliano 1997] is made of four distinct components:

1. IPERedit, a WYSIWYG editor that allows the building and maintenance of the hypertext. It is a full visual environment that totally hides to the user the management of the distinct files and media the hypertext is composed of. IPERedit uses a private representation for hypertext (the .AEH file) but it can easily import and export file written both in HTML and in Microsoft Rich Text Format (RTF) [RTF 1994] using the Windows Help Convention (WinHLP) [Microsoft]. HTML pages can be downloaded directly from Internet thanks to a HTTP-browsing capability integrated into the editor.
2. IPERreader, a read-only browser to distribute the hypertext over traditional media like diskettes or CD-ROMs: all the browsing capabilities of IPERedit are provided.
3. IPERserver, a gateway that allows the browsing of an hypertext in AEH format stored in a standard WWW server by a HTTP connection.
4. IPERupload, a server side demon that allows the upload of a hypertext into a WWW server with a simple click of the mouse button. Remote user identity is ensured by a simple MD5-based protocol.

IPERedit and IPERreader have been developed using Borland Delphi, a visual environment that allowed a fast prototyping of the product in the MSWindows environment. IPERedit and IPERreader are fully supported under Windows 3.11, Windows95 and Windows NT 3.5. IPERserver and IPERupload consist of a library of CGI (Common Gateway Interface) scripts developed in C that at present run over Digital UNIX 3.2; they are nevertheless portable over other flavors of UNIX, and over other systems. IPERupload has been easily installed on a SUN to distribute hypertexts to the students at the University of Udine.

Our main goal in developing IPERedit was to help the user not to waste time in taking care of the different files of which a hypertext is made of. The user works all the time with a unique object called the hypertext and all the objects inside the hypertext are stored in a single file: this make the distribution and the maintainance of the hypertext extremely simple. In order to achieve this goal we defined a private binary file format called AEH (Advanced Encapsulated Hypertext) that allows the encapsulation of all the object inside the hypertext. While developing this format we strongly kept in mind the need of an easy conversion to and from HTML and RTF formats.

3.1 IPERedit

IPERedit is a WYSIWYG hypertext editor that has two distinct components:

- the *main window* (see Figure 2) provides a whiteboard on which the hypertext is displayed. The menu bar allows the usual operation, such as opening and saving the hypertexts. A toolbar provides hypertext-related functions: in the reader mode it contains only the basic instruments for navigation, while in the editor mode it provides buttons for hypertext import, objects management, keyword management and switching between browsing and editing modes.
- the *toolbar window* (see Figure 2) provides page-related functions such as text and paragraph formatting and tools for inserting and managing objects into the hypertext. The toolbar appears as soon as the user switches from reader mode to editor mode.

An object oriented approach has been followed to manage the variety of elements inside the hypertext. Each complex item (such as images, image maps and links) can be found in the object table and the user can modify its properties at any time. Inside an hypertext you can find the usual objects of a networked hypertext such as images, image maps, tables, frame sets and multimedia players for audio and video. Links can drive to another page in the hypertext, to a standard Internet URL or to executable or compressed files embedded into the hypertext. Linking objects inside the hypertext is a full visual operation: a window helps to choose from the objects database by giving a preview of the link destination.

3.2 IPERreader

IPERreader is a read-only version of IPERedit. It has been projected to distribute hypertexts in AEH format by traditional means such as diskettes or CDROM. User can browse trough the hypertext using the navigation panel and can access to the keywords database. It's possible make a global search trough the keywords or choose directly a keyword between the sets of keyword inserted by the hypertext author. IPERreader act over the hypertext as the WinHLP interface do.

IPERreader setup information can be customized from the author of the hypertext to display hypertext related information during the installation in a local environment. This allows the distribution of the hypertext together with IPERreader has a single integrated package. IPERreader can be used as a context-sensitive help interface for MSWindows programs using the Microsoft Dynamic Data Exchange. This allows program developers to use IPERedit as a hypertextual help editor for Windows applications.

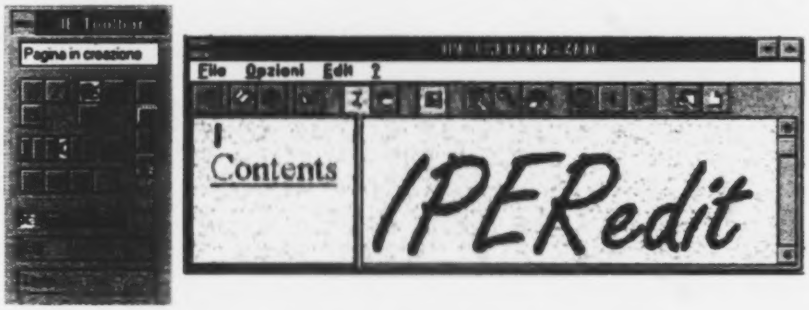

Fig. 2 - IPERedit, the main window and the toolbar window

3.3 IPERserver

IPERserver is a simple Common Gateway Interface (CGI) script that provides on-the-flight conversion from an AEH file to HTML. This make the AEH files stored into the file system of a WWW server accessible to any HTTP client.

As shown in Figure 3, each link of the AEH hypertext is translated by IPERserver into a dynamic self-request. This means that by clicking the link, IPERserver is invoked to display the requested page of the hypertext. Parameters specifying the requested hypertext and page are sent to IPERserver via extra path information, as defined by HTTP 1.0 protocol.

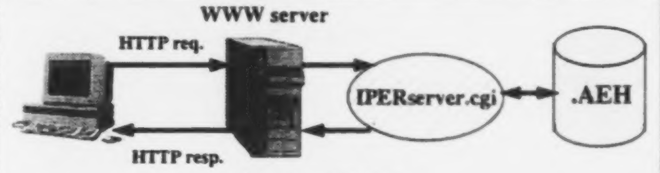

Fig. 3 - IPERserver

3.4 IPERupload

In order to provide an easy way to maintain and distribute hypertexts on WWW we developed a secure CGI front-end to upload AEH files in an hypertext. Trough a connection with IPERupload, an authenticated user can upload a new hypertext or modify or delete an existing one. Uploading is as simple action (the click of a button) in the upload window of IPERedit. The only requirement for the user is to have previously and properly configured his profile providing username, password, the remote location of the WWW server and the directory in which the IPERupload CGI is located. IPERedit can be distributed pre-configured for a WWW server so that the user need only to provide username and password. Hypertexts uploaded onto a WWW server are immediately available for distribution over the Internet through the IPERserver gateway.

As we provide a gateway to write on the file system of a WWW server from a remote IPERedit client, we need an authentication framework to protect unwanted accesses to the file system of the server. Each hyperwriter is uniquely identified by a user name, and a password is required to add or overwrite a hypertext stored in a WWW server. The password is never sent in clear over the network, but an MD5 hash of a challenge phrase is used to authenticate the user to the server. This will protect the password from eavesdroppers that could observe packets flow over the Internet.

4 Applications

While we are in the process of experimenting IPERtool and of adding new features, we have used it for a number of applications.

A hypertext for teaching the C programming language to students at the first year of a master degree in computer science engineering has been written at Politecnico di Torino using IPERtool. It contains about 2.500 nodes; if it were written in HTML it would have been composed of 2500 different files with the obvious related management problems, but in our case it is only composed of a single file. This application, under the form of two floppy disks that contain also the IPERtool browser, has been distributed to the students both at Politecnico di Torino and at the University of Udine, and it is available on the Web of Politecnico di Torino.

Besides the educational applications, in order to provide a wide testbed to the IPERtool authoring system, it has been provided to Ph.D. students at Politecnico di Torino to create and maintain their personal home pages. We are evaluating the feasibility of using IPERtool as the way to provide real time update to the official courses program of our University, allowing direct access to the courses description hypertext for the teachers of Politecnico di Torino.

5 Conclusions and Future Work

The experimentation of the various features of IPERtool will give us a report of the positive and negative characteristics of the tool. We are in particular interested in the reaction of hypertext authors with no computer science background to see if IPERtool is as easy to use as we intended it to be.

Future work is also directed to provide full compatibility in import/export HTML 3.0 Netscape extensions and to solve minor bugs related to table management. To provide an higher level of security in writing the WWW server file system, a public key based authentication framework will replace the actual based on MD5.

Abstract : This paper describes an Internet based learning environment for Information Systems (IS) Analysis and Design to supplement classroom based instruction. In this scenario, the relationships among the learning task, the pedagogical model and the supporting technology become a central issue for investigation. The learning environment makes use of on-line multimedia instructional materials, of support tools targeted to engage in the IS design task, including a library of design projects, and of communication and collaboration facilities, including a shared blackboard and videoconferencing. Preliminary evaluation of the adopted pedagogical model with respect to the one applied in the previous editions of the course, by taking into account the students evaluations and course grades is discussed.

1. Introduction

Many attempts have been made in the last years to promote distance learning environments by using both telecommunication and data networks. Among the technologies proposed to support learning at a distance, we identify two extreme situations: television channels and ISDN networks. The first solution does not afford real time interactions between learners and teachers but it allows the wide distribution of lectures at low cost. On the contrary, the second solution privileges real time interactions but at a relatively high cost. Both approaches are typically complemented by electronic mail systems that provide asynchronous communications channels to send questions and receive answers or feedback on assignments. Some communication solutions initially aimed at addressing the needs of distance learning have gradually been adopted in more conventional settings and have resulted in the increasing number of "on line" courses that substitute or integrate the learning experience offered in the classroom. Internet has opened up a much more flexible and rich space for this kind of experimentation, by expanding the range of media formats available for instructional materials and by allowing participants in a learning experience to establish new patterns of communication. However, the pedagogical model underlying traditional distance learning solutions is often a lecture-based one, under the assumption that the most important events in a classroom are the teacher talking and the questions from the learners. The shortcomings of such "delivery" model of instruction are made apparent by recent theories that emphasize the social and cultural nature of cognition and regard learning as an activity based enterprise [Brown et al.,1989]; [Lave & Wenger, 1991], in which knowledge is created by collaboration among social actors who contribute towards the creation of shared understanding of a problem and to its solution.

This paper describes an Internet based learning environment developed for undergraduate students of Information Systems (IS) Analysis and Design to address some shortcomings of classroom based instruction that are especially evident when the learning task is design and a high number of students are enrolled. Design typically requires extensive revisions and feedback from the instructor, and when the complexity of the system to design is relatively high, it often has to be carried out collaboratively by teams of students. All these aspects tend to be penalized with conventional, classroom based approaches to learning.

Current communication and groupware technologies can support approaches to learning enriched by a cooperative mode of interaction based on audio, video and shared documents. Most importantly, such technologies may also afford instructional interactions which otherwise would be extremely difficult, if not impossible, to implement in a traditional environment. Surveys and explorations of the form of support that computers afford to collaborative learning are provided in [Silverman, 1995] and [Crook, 1994]. There are some experiences in the use of distributed collaborative technologies for students engaging in engineering design [Watable et al., 1995], even in a distance learning framework [Andriole et al., 1995], that, though still exploratory, present encouraging findings. Another experience in the use of asynchronous learning networks for information and software systems design is described in [Andriole et al., 1995]. The learning environment is designed to organize materials, classroom discussion and assignments and create a continuous "on line" course. The need of integrating design tools and of making available records of prior teams collaborations for designing a decision support system is emphasized in [Silverman, 1995]. An experience focusing on collaborating on the Internet based on desktop videoconferencing in the context at a distance learning course produced by the Open University is described in [Alexander & Mason, 1994].

This paper can be situated in the context of attempts to integrate resource based learning and low cost collaboration technologies to test both the technological feasibility and the pedagogical effectiveness of the resulting environment. In this scenario, the relationships among the learning task, the pedagogical model and the supporting technology become a central issue for investigation. The learning environment for IS analysis and design proposed in the paper makes use of on line multimedia instructional materials, a set of support tools targeted to engage into the IS design task among which is a library of design projects, and of communication and collaboration facilities, including a shared blackboard and videoconferencing.

2. A Pedagogical Model for Learning IS Design

The proposed pedagogical model has been set up to support an introductory required course in Information Systems Analysis and Design, which is attended by a large number of undergraduate students (typically around 100 per section) in electrical and computer engineering. The main objective of the course is to learn a methodology to develop an IS project, from the requirements analysis phase to the design of the data structures, to the development of a system prototype. The course also covers the theory of relational databases, the fundamentals of a DBMS (i.e. Microsoft Access) to prototype selected aspects of the information system and the architectural concepts of computer networks that are most relevant to IS design (e.g., for performance evaluation). Whether a course can considered successful or not is largely a matter of the overall level of interest and engagement generated in the learners, who can thus find the intrinsic motivation to overcome the technical difficulties and reach the level of competence required. To this aim it is important to structure a learning experience that is authentic enough to be motivating and still technically well supported. It is not a case that dimensions such as interest, perceived usefulness of the contents, quality of the materials, efficacy of their use are now included in the institutional course evaluation forms, to gather feedback from the students on the quality of the overall learning experience. How to incorporate such "metaobjectives" in a pedagogical model to address the main learning challenges for novice IS designers and the role that technology can play in this enterprise is the main concern of the paper. In the following, peculiar aspects of the IS design learning tasks are elucidated to discover pedagogical and technological opportunities.

A first issue to consider is that effective communication in IS analysis and design requires media more expressive than text, because concepts of networks (e.g., queue theory for performance evaluation) and formal description techniques (such as automata or Petri nets for modeling system's behavior) have a strong dynamic component difficult to capture. Using hypermedia (e.g., colour, sound, animation, and links) prepared by the instructor to illustrate such concepts in the classroom is therefore the more adequate solution, and a fundamental part of the pedagogical model with respect to the communication issue. However, to sustain the immediate communication benefits such materials should be available for personal study and revision, given the difficulty in taking notes in real time.

A second issue concerns facilitating learning by expert modeling of the task and of the related metacognitive activities [Collins et al.,1989], especially for those aspects not fully addressed by the design methodology, that are: 1) capturing the requirements's specification in a conceptual model of the system and 2) the transition from the conceptual model (functions and entities) to the logical architecture of the system to implement (i.e., the design of software modules and tables). Concerning design metacognition, a skill to develop is how to verify the consistency and completeness of the system's specification, and monitoring that heuristic criteria of good design are met. However, in the context of classroom based courses, the instructor can model for the learner the above activities only few times, focusing on selected examples. Also, it is difficult for the instructor to interact extensively with the students for individual guidance on their projects and to provide feedback at intermediate stages of design, due to the high number of students and also to the fact that part of the available time is spent in repeated patterns of clarifications to different groups. A first solution to this problem is to create a base of annotated IS projects produced by the students in the former years of the course [Faro & Giordano, 1996]. A variety of cases available for inspection can foster cognitive flexibility [Spiro et al., 1988]. In addition, the base opens a "window" on the reasoning processes of peers and can indirectly support metacognition.

A sound pedagogy must take into account that IS design is inherently a collaborative task. Because of the complexity of the systems to design many actors with different purposes and competencies are involved in the process: designers, clients, users, implementors. Students are therefore encouraged to undertake the major assignment of the course, i.e., the development of a project, in groups of two or three; this form of cooperation is important first because the team tries to sort out collaboratively issues regarding the interpretation and application of the design methodology; and second because it provides a microworld of the realities of professional life as designers, in which communication and reasoning skills can be cultivated. On the other hand, especially in classroom based courses with large numbers of students there is often a lack of awareness regarding what other teams of peers are doing. This rules out opportunities for exchanging design experiences among teams who are tackling problems in similar domains.

Models of cooperation based on teams of students tackling their own design project, e.g., [Dietrich &Urban 1996] still do not address the problem of limited exposure to varied design situations and design solutions and of how to scaffold the learner. Concerning scaffolding, we have proposed to integrate this aspect directly in the IS design methodology, by introducing a method of analysis of the system based on stories that formalize the interactions taking place in the IS system [Faro & Giordano, 1996]. The integration of story based reasoning in a methodology for IS design provides a well-received framework that the learners use to focus their attention in selected but meaningful parts of the system, thus reducing the cognitive load involved.

Having the above scenario in mind, IBLEDIS (Internet Based Learning Environment for Designers of Information Systems) has been deployed to supplement classroom lectures by implementing some components of the above pedagogical model to enhance and augment the experience of each individual learner.

3. IBLEDIS: Architecture and Use Cases

IBLEDIS is organized according to three main groups of functionalities, as shown in [Fig.1]:

1. Support to the students with respect to the contents and organization of the course, targeted for the initial part of the course, in which the fundamental concepts to engage in the design task must be acquired.
2. Tools and resources to scaffold the design task, from the conceptual and technical point of view.
3. Functionalities to address public and private communication and collaboration needs.

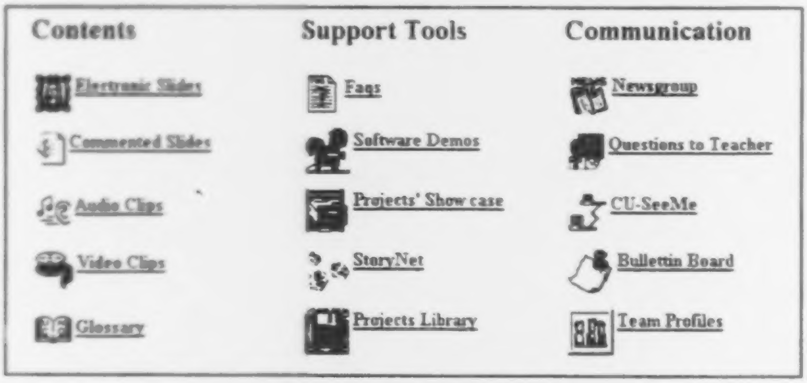

Figure 1: IBLEDIS main menu

Students access IBLEDIS using Netscape from their PC, as illustrated in the architecture of [Fig.2], either to download the learning resources (contents and design support tools) or to use them on line, likewise a stand-alone hypermedia program, the latter choice being made to facilitate students who can only access IBLEDIS from the university computing services. To make full use of the IBLEDIS resources the clients PCs need the client versions of the software VDOlive, Iwave , and Cu-see-me, respectively managing videoclips, file audio, and videoconferencing. A Connectix Quickam is used for the video options of the Cu-SeeMe software. A PowerPoint viewer and Lotus ScreenCam player are used to view the hypermedia instructional materials.

Figure 2: IBLEDIS architecture

At the beginning of the course students are asked to watch a short introductory videoclip, currently produced with VDOLive Technology, which mainly serves to highlight the relevance of the main topics of the course. The students are requested to study each topic by using as learning resources the electronic slides projected during the lectures. The slides, produced in MS PowerPoint, can be either downloaded as the complete set for each topic or they can be viewed on-line. In the second option, the student can ask to listen to the audioclip related to the slide by clicking the relevant icon. These audioclips are managed as separate files by the VocalTec Iwave client-server technology. The FAQ icon is context sensitive and provides links to the FAQs related to the slide. The glossary is also available to retrieve a definition of the unknown terms and to allow the cross-referencing of topics with the FAQs. The bibliography icon is also context sensitive and provides the references to sources and articles for further readings on the topic at hand.

A News Group facility is available to post question to the teacher and to all the other learners or to browse for useful posted messages. The news group has been organized according to discussions on specific topics and project proposals. Announcements regarding "public" feedback sessions are posted in the bulletin board.

After the students have acquired the basic theoretical concepts, they are requested to develop in teams a project that they will present for their final exam, and the core of the design learning experience begins. This phase is characterized by a change in the collaboration needs, in the tools to support learning and in the kind of feedback required from the instructor. As outlined in the previous section, the students' Projects' Library turns out to be a critical resource to support the phase of conceptual modeling (e.g., system's analysis) by increasing the number of available cases and solutions. These projects are a significant portion of the accumulated memory of the course, and are indexed by domains, by patterns of use-stories of the information systems. Projects developed in electronic format can be downloaded. The projects' library plays an important role in the initial phase of the design exercise, in which teams choose their domain application and examine the available relevant projects to check for aspects that they have not captured in their initial conceptual model of the IS system. Once the main components of such model have been outlined, team collaboration focuses on deriving the data flow diagram, the entity model, on dimensioning the system and on developing a prototype.

In this stage the students start asking for the available SW tools to assist the project development. Currently, two tools developed in our lab, i.e., StoryNet, a design environment to structure the project in stories, and a visual program to perform computer network performance evaluation are given to the students. Other tools are available at the computing center to prototype the information system. To facilitate their use, and minimize the

BEST COPY AVAILABLE

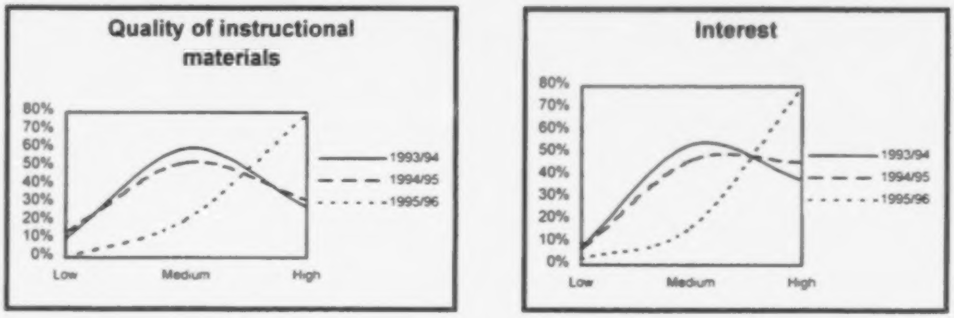
time spent on lab demonstrations, a set of software demo clips is available on demand via Internet aiming at demonstrating how the tools work. These demos, likewise the commented slides, have been produced with LOTUS ScreenCam technology, which allows recording all the activities taking place on the screen, including audio comments. The students also have the possibility to ask the members of their team or the instructor to open a synchronous working session by using the conferencing and the shared blackboard facilities offered by the WhitePine version of the Cu-SeeMe software.

4. Evaluation and concluding remarks

IBLEDIS partially implements the pedagogical approach to learn information system design discussed in the former section with respect to providing a flexible access to the learning resources and to fostering various forms of collaboration. Regarding IBLEDIS effectiveness in supporting engineering students to learn information systems design and in addressing the quality dimensions of the instructional experience outlined in section2, we have some preliminary results based on patterns of use, students' evaluations, and grades measuring the quality of the final design. Among the components of the environment mostly appreciated are for their usefulness: 1) the slides distribution via Internet together with related audioclips; 2) the commented slides related to the illustration of dynamic concepts; 3) the use of the newsgroup facilities to discuss the projects proposal; and 4) the consultation of the library of the already developed projects.

From the comparison of the evaluation forms of the course of the last three years we have some indications on how some components of the pedagogical model, in conjunction with IBLEDIS have affected the students. Evaluation forms in the academic year 1993/1994 correspond to an instructional condition of a traditional approach to the design classes; in the academic year 1994/1995 the story based scaffolding was introduced and the set of electronic slides with animation was used only during the regular classes; in the academic year 1995/1996 these materials were made available via IBLEDIS, together with the projects' library and the other above described support tools.

Students evaluations of the course organization and of the supporting learning environment concern quality of instructional materials, interest in the course, comments on the perceived quality of design labs. Quality of instructional materials in the third condition has been considered high by the 89% of the students [Fig.3a]. The significant variation from the patterns of the previous years can be considered an effect of IBLEDIS, in terms of organization and direct availability, because the text based materials have been unchanged, and the same electronic slides were used, but not distributed to the students in the year 1994/1995. A promising effect has been noticed in the increased students' interest [Fig.3b] and in how the quality of the labs are perceived [Fig 4].



(a) (b)

Figure 3: Student's evaluation of quality of instructional materials (a) and interest in the course (b)

This might be an effect of more time available for the instructor to model ill-structured aspects of design, and by an increased readiness of the students that, based on better materials and story-based scaffolding, overcome more easily some initial difficulties. Concerning the grades, we have noticed an interesting effect according to which in the second and third condition more students perform better, and the number of students whose performance is average decreases. Of this set, most students can move up in the grade scale, whereas some tend to get grades slightly lower than they used to get in the first instructional condition, i.e., without following the story based methodology and without the resource support of IBLEDIS.

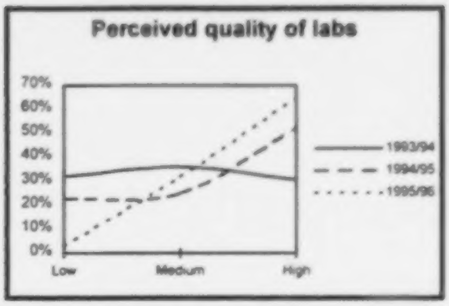


Figure 4: Student's evaluation of quality of course labs

A possible interpretation is that this is due to a better discriminatory power in the quality of the project entailed by the story based methodology. This preliminary figures have been derived by standard evaluation forms that were not specifically designed to investigate IBLEDIS, and from the official grades.

At the current stage IBLEDIS can be considered successful regarding supporting asynchronous collaboration, in the form of clarification and interactions with the instructor, in increasing the number of perspectives that may be offered on the same design issue; and to increase in the overall number of design situations to which each individual learner can be exposed. Another issue requiring investigation is whether patterns of interactions and collaboration (among learners, and among learners and instructor) can be effectively and naturally established over Internet based on the videoconferencing component, and enrich the processes that are instantiated within a face to face group meeting while jointly producing an artifact. So far, the implementation in IBLEDIS of our pedagogical model is not full fledged. The current development efforts are targeted on creating a project library that has the full functionalities of a case based reasoner and is accessible from remote, and on including in making it evolve based on the students and instructor annotations.

Abstract: This paper reports on key issues examined by a cross-disciplinary research team involved in the development of Virtual-U, a Web-based intentional learning environment for post-secondary course delivery which supports collaborative learning and knowledge building. Section 1 describes Virtual-U itself. Key research issues are presented in section 2. These range from user interface design questions such as navigation support and use of multimedia to the pragmatics of communication and social interaction in shared workspaces. Addressing these issues necessitates a broad cross-disciplinary research approach that informs the design process in an iterative testing/design cycle described in section 3. In section 4, we discuss a possible course for the evolution of Virtual-U into a more richly textured collaborative learning environment, using a smooth upgrade path and interactive design to maximize transfer of knowledge and experience as the system grows.

1) Background

Virtual-U is a World Wide Web-based integrated set of software tools and templates enabling the creation, delivery and enhancement of on-line courses that is being developed under the direction of Linda Harasim and Tom Calvert by the Telelearning National Centre of Excellence. Virtual-U is intentionally designed to enable and facilitate asynchronous discussions, collaborative learning and knowledge building (see [Harasim, Hiltz, Teles, and Turoff 1995] for background). Users require a workstation, a Web browser (Netscape Navigator or Microsoft Internet Explorer), and access to the internet. Course delivery requires setting up the course on a Web server hosting the Virtual-U software. Virtual-U's current functionality includes the following components:

- Creating course Web pages
- Structuring interactive discussions and collaborative activities among students, teacher and external participants
- Creating shared resources for knowledge building
- Class management and evaluation

Course design support includes guidelines for setting learning outcomes, instructional techniques, evaluating learning outcomes, "netiquette", discussion or project group design, learning activity design, and course syllabus creation. Ancillary discussion groups can be set up within Virtual-U to allow groups of teachers and/or support staff to discuss instructional strategies, support issues, etc. Course design support consists of guidelines for setting learning outcomes, instructional techniques, evaluating learning outcomes, netiquette, group design, activity design, and course syllabus design. There is also a facility to allow users to share their own tips and experiences with other users.

VGroups is Virtual-U's Web-based computer conferencing component. Using Vgroups teachers can create discussion groups that mediate students' on-line communication according to different discussion modes such as topical discussion, debate structure, role playing, etc. Activity templates and tags can help to scaffold particular activity types. Discussions can be set up as course-related or entirely social (as in the students' informal "Cafe" discussion environment). Messages can be sorted and viewed by topic (i.e. "thread"), date or author (See Figure 1.). Users can imbed either URLs or HTML in messages to incorporate hypermedia links to other Virtual-U Web pages or other Web sites. This is one of the ways in which Virtual-U supports the learners' interaction with shared resources. Other means include a file manager for uploading or downloading files, tools for creating concept maps and tools for annotating documents. Virtual-U's on-line grade book provides a class management tool that is configurable to allow students to view their own grades as well as a graphical representation of the class distribution, or to read a qualitative assessment of their work by their teacher.

Figure 1: V-Groups conference messages sorted by thread.

Class management and evaluation is supported with an on-line grade book which can allow students to view their grades, the distribution of grades as a bar chart, and qualitative assessment of their work. Instructors may manage grades entirely on-line or upload from a local spreadsheet to the grade book.

Navigation of Virtual-U is based on a campus metaphor (see Figure 2) to create a sense of familiarity for newcomers to on-line learning.

2) Research and design issues

Virtual-U is being developed within an academic context to provide a tool specialized for the delivery of post-secondary courses. The developers are sensitive to the broad range of design issues that might determine the success or failure of the software in mediating the learning process. In order to insure that Virtual-U effectively supports the pedagogical principles of knowledge building and collaborative learning, a Cross-Disciplinary Research Design group (CDDR) was assembled. Current members of the group are drawn from Communication/Education, Cognitive Science/Psychology and Computer Science. Our intention is to expand this group to include a broader range of the Social Sciences (e.g. Sociology/Ethnic Studies).

In collaboration with the Human-Machine Interface group of the Institute for Robotics and Intelligent Systems, CDDR is applying new methodologies to the study of the perceptual, cognitive, and social aspects of shared multimedia learning environments. Much of this work is at an early stage of development, but it has already had a significant impact on the design of Virtual-U.

a) Navigating in the virtual university.

One focus of work deals with the interaction of perceptual systems and higher-order mental representations (the so called "cognitive architecture"; [Pylyshyn 1991]) of events in space. A major cognitive framework for individuating, visualizing, and keeping track of different items of knowledge (such as who said what in a conference or what items of data go with what) is the use of real 3D spatial locations. We use space both literally (as in the desktop or office model of data organization) and also figuratively. Examples of the latter includes such techniques as mentally locating different facts and premises in certain imagined spatial loci -- a technique widely used in mnemonic aids, and the use of spatial location in reasoning where so- called "spatial paralogic" provides an important scheme for keeping track of different components of a problem. Understanding and supporting the effective use of spatial reasoning with perceptual cues could greatly enhance users' ability to understand complex problem domains.

Existing hypermedia navigation tools utilize high-level cues (e.g. landmarks, memory aids, and shortcuts) to aid users in determining their position within a complex hypermedia document. This often requires a difficult cognitively mediated dynamic mapping task to be done in tandem with users' main tasks, straining users' attentional

BEST COPY AVAILABLE

capacity. In daily life, a set of low-level mechanisms enables us maintain a consistent mental model of a stable world despite rapid and frequent shifts of retinal images due to eye, head and body movements. Recent work in Cognitive Science [Pylyshyn 1994]; [Goodale and Milner 1992]; [Bridgeman and van der Hejiden 1994] has led to a better understanding of the interaction of perceptual events in visual space and central processes. In collaboration with basic researchers, we are applying these theories to the design of data spaces for improved understanding and easier navigation. One example of this is a Web navigation tool called CZWeb, which uses animation, hierarchial organization, and detail-in-context views to provide a dynamic spatial representation of portions of the Web.

b) Understanding modes of interaction of multiple users in shared spaces

Optimizing social facilitation and active collaboration in educational environments requires users to integrate the synchronous/asynchronous actions of multiple users in the same knowledge space. This requires users to accurately attribute repercussions of an action to the correct cause and the correct actor. The critical theoretical issues again revolve around users' internal representations of objects and events in shared perceptual, cognitive, and motor space. Spatial indexing (FINST) theory can help us to find low- level cues to tie together effects and actions, allowing multiple users to operate on the same information set in a cooperative manner. These mechanisms have been examined in the laboratory [Pylyshyn, Burkell, Fisher, Sears, Schmidt, and Trick 1993], but remain to be tested within the context of Virtual-U.

c) Information channeling in a multimedia environment.

Knowledge building tools need not be limited to graphical displays. The effective use of sound can increase the amount of information that can be understood, while reducing the demands placed upon the already overburdened visual channel. Optimal use of auditory displays requires a greater understanding of how they interact with visual displays in scene understanding, active perception, and direct manipulation tasks. Previous work by [Fisher and Pylyshyn 1994] and others has suggested that different tasks appear to utilize different multimodal integration cues, and so may evaluate visual and auditory sources of information in different ways. Since computer display environments often produce errors in these cues (e.g. asynchronies, location errors and poor quality renditions) this can affect the interaction of sonic and visual displays. Ongoing research by the IRIS human interface group on spatial sound displays and sonification of work environments should transfer to a variety of telelearning applications, particularly in the development of virtual laboratories for learning technical and performance skills.

d) Communication strategies for collaborative learning.

The low-bandwidth of computer-mediated communication tools can give rise to conflict and misunderstanding among users. The impact of this on existing networks (such as USENET) is great, and extension of networked communication technology to new user groups exacerbates the problem. Another focus of our work applies Psycholinguistics models [Grice 1975]; [Clark and Wilkes-Gibbs 1986] to address the pragmatics of social interaction and communication over limited bandwidth channels. Face-to-face communication is to a great degree mediated by conversants' knowledge of their common ground of shared referents, which is largely created and maintained by the use of non-verbal cues such as expression and gesture. In designing a collaborative environment, care must be taken to insure that the "social bandwidth" that enables users to disambiguate their language (a process known as "grounding" [Clark, and Brennan 1991]) is maintained. An examination of the V-Groups productions from different groups of users (i.e. completely on-line vs. mixed-mode) combined with laboratory testing will help us to determine the effects of the bandwidth limitations that are imposed by technology on communication, and how students compensate for these limitations. This in turn will help us to better design the interface for more effective communication.

e) Cultural and social factors in the use and acceptance of distributed education.

Acceptable metaphors for learning may differ between various ethnic groups, socio-economic strata, and age cohorts. In addition, computer-supported collaborative learning will result in the formation of study groups that may include users who differ in age, sex, ethnic and cultural backgrounds. We are actively seeking to expand the diversity of our user community so as to learn ways to better support the inclusion of diverse user populations. Ongoing assessment should be conducted during implementation in order to insure that the interface is optimized for a diversity of users.

3) Process

a) Iterative design.

A lack of data from large-scale real-world use of comparable collaborative learning environments required us to begin by building a relatively simple system in a short time frame that could be tested in a broad-based field testing program. Results of these tests would lead to design changes that would in turn be tested in field sites and in our interface testing laboratory. This insures that design changes benefit from the input of real users of the system.

b) Large-scale field tests

A major difficulty in building a robust general-use computer-supported collaborative learning environment is that it must serve a broad diversity of students, instructors, subject materials and instructional styles. Small-scale user tests are unlikely to provide a representative sample of this heterogeneous population. Our current field testing program serves approximately 730 students, and is as broad-based as possible.

c) Integrated data analysis

Converging evidence from a variety of measures and testing situations is combined to give the broadest possible perspective on the utility of Virtual-U. Field site participants are surveyed by questionnaire, and their interactions (i.e. server requests) with the Virtual-U Web server are recorded. Parsing the server requests into user actions is problematic, as a simple activity may generate a number of hits. User testing data can help to establish correspondence between activities and server requests by comparing patterns of Web server requests in the field and in the laboratory. Identification of characteristic patterns of server requests that are associated with particular situations and user actions allows us to bridge the gap between laboratory and field studies, allowing more precise analysis of events in the field.

Taken by itself, this data set provides useful information about overall user satisfaction and use patterns. In addition, the quantitative data set can be used as a window into the rich qualitative dataset of instructors' and students' productions in conferences and elsewhere in Virtual-U. By identifying specific populations of users and situations, the quantitative data analysis can select subsets of conference productions for the more resource-demanding qualitative content analysis using Nudist or similar analysis tools.

Field testing provides us with a dataset which has excellent external validity, insuring representative sampling of the broad population of users and uses. It has three drawbacks, however. First, it is difficult to conduct true experiments due to the overhead in distributing and supporting multiple versions of the system (e.g. control and experimental versions). Second, collection of useful performance variables such as reaction time, individual keystrokes, etc. is impractical due to the number and wide distribution of users over the Internet. Finally, the lack of control over (or even knowledge of) obscuring variables such as location, data transmission speed, system characteristics, etc. limits our ability to assign observed differences in performance to system variables. Thus,"fine tuning" the system requires laboratory testing, which must then be examined within the context of the field site data.

4) Future Work/Enhancements/Directions

The final aspect of the Virtual-U design philosophy that we would like to discuss is the need for a smooth upgrade path. Current field site students and instructors should benefit from their expertise with older releases as they make the transition to our more advanced designs. While the final design of each release will be determined by laboratory and field testing results, current design plans are to augment the collaborative aspects of Virtual-U by the use of specialized activity scaffolds.

Our current version of V-Groups is relatively unstructured to provide maximal utility for a wide variety of collaborative tasks and methods. Structure is provided by topics, threads, and keywords within a conference, and conferences themselves are structured heirarchially. Within a discussion, students and instructors have complete freedom of use of these organizational cues. This free-form discussion requires users to exhibit considerable discipline in their implementation of the organizational cues provided.

Future versions of V-Groups are likely to maintain this level of freedom for "brainstorming", while providing a richer language of reference to previous messages. We can then use the pattern of interconnections between messages to structure a graphical depiction of the knowledge space created by the free-form discussion. We are currently testing CZWeb, a Web structure visualization tool developed at SFU that provides many of these functions. CZWeb provides users with an animated map of a potion of Web space, where pages and groups of pages are displayed graphically with visible links. Users can manipulate this map, grouping pages in nodes, zooming in and out of regions of the map and so on.

The graphical depiction of a largely text-based set of collaborative messages is the first step towards the creation of a graphical knowledge space, which can then be manipulated by more structured collaborative tools such a planned debate tool. The knowledge space thus created provides a conceptual "lumber yard" which can be used for hypothesis creation and testing, as users create new links that may themselves contain meaning (e.g. "is an example of", "supports", "is a test of" etc.). Other types of tools might instantiate specific roles or perspectives on the data space with a customized quiver of specialized productions possible. Students might adopt the role of the Skeptic, or the Empiricist (or the Fool), operating upon the data space in the appropriate manner.

Much of this work is in the early stages, and will benefit from the experience of the field site participants and from input from colleagues in a wide variety of fields. We are seeking to expand the number and diversity of CDDR members, particularly in the neglected areas of the Social Sciences that deal with cultural and social issues. As we succeed in this, we will no doubt experience increased difficulty in bridging the gaps between our own members. Our hope is that this effort will bear its rewards in an effective collaborative learning environment, deeply rooted in the theoretical and practical aspects of distributed collaborative learning.

Abstract: This paper discusses the results of a study to determine the effects of prior computer use, student rank, and differences in levels of field dependence/independence on learning outcomes within a hypermedia program for preservice teachers in special education. No differences were found for achievement, construction of concept maps, on-line test scores, or problem-solving scores which were related to prior computer knowledge, student status, or learning styles. Participants with differing learning styles used the program an equivalent amount of time and accessed information similarly. Differences were found in the proportion of time they spent across two of the four hypermedia instructional components but these differences did not influence learning outcomes.

1 Introduction

In spite of current enthusiasm for hypermedia-based instructon, most researchers agree that insufficient evidence exists to determine whether outcomes match the proclaimed promises of hypermedia. Because hypermedia can provide a flexible, efficient, nonlinear, and associative learning environment, educators have embraced its format without sufficient research on its effects (Liu, 1994). As stated by Harmon and Dinsmore (1994), "most developers assume that, because hypermedia *ought* to be good for instruction, it *is* good for instruction" (p. 157). The excitement for the approach largely rides on the notion that learners *can* and *will* customize their instructional choices in a hypermedia program to fit their preferences and learning styles. Limitations to hypermedia have also been cited (Jonassen, 1989), and it may be that hypermedia is not suitable for all learners.

Research is in its infancy in studying relationships of learner characteristics, hypermedia formats, patterns of use, and learning outcomes. To date, existing research is sparse on a number of these factors and what exists is difficult to synthesize due to differences in lengths of treatment, subjects, features of the hypermedia programs, and outcome measures. This study focused on learning outcomes for adult learners utilizing a robust hypermedia program in a lengthy treatment.

2 Research Questions

The study was designed to address the following research questions about hypermediated learning:

(a) Is there a relationship between prior experience using computers with learning outcomes of students using a hypermedia-based instructional program?
(b) What effects does a hypermedia-based instructional program have on learning outcomes for preservice teachers representing two class ranks and different levels of field independence/ dependence?
(c) Do preservice teachers with different levels of field independence/dependence utilize a hypermedia learning environment differently with regard to engagement time and patterns of accessing information?
(d) Do preservice teachers with different levels of field independence/dependence perform differently in a hypermedia learning environment with regard to mastery of content and on-line problem-solving activities?

3 Treatment: The Hypermedia Instructional Program

3.1 Instructional Content and Purpose

The hypermedia program used in this study was *Perspectives on Emotional and Behavioral Disorders* (Fitzgerald, Semrau, Kraus, Nichols, & Glickert, 1995). The materials utilize a case study format featuring three youngsters with behavioral problems in school settings. Each case study includes an opening challenge scenario and case information presented via software, audio and video support materials residing on a videodisc. Users explore information from a variety of theoretical perspectives by: (1) observing children in a variety of situations; (2) "interviewing" their teachers and parents; (3) seeking background knowledge and case information; (4) comparing and contrasting multiple theoretical views; (5) hearing "experts" discuss the cases; and (6) engaging in problem solving and planning activities within the case studies.

3.2 Underlying Instructional Design

Through the interactive case study approach, the learner is expected to develop a cognitively flexible understanding of the complex, multiple theories and approaches used in formulating intervention programs for students with emotional and behavioral disorders. "Cognitive flexibility" involves the *selective* use of knowledge to *adaptively fit* the needs of understanding and decision making in a particular situation. "Ill-structuredness" means that many concepts (interacting contextually) are pertinent to a specific case, but that their patterns of combination are inconsistent across case applications of the same nominal type (Spiro, Feltovich, Jacobson & Coulson, 1991). The instructional approach utilized in this program strives to develop cognitive flexibility to enable the learner to construct knowledge based on complex and irregular situations. It focuses on the construction of knowledge structures and the application of that knowledge structure to problem solving.

Cognitive flexibility can be enhanced through effective design of hypermedia programs by situating problem solving in authentic case scenarios, providing factual and procedural knowledge within the discipline, scaffolding the learner through guided activities and embedded structure, and modeling the reasoning processes of experts. To evaluate the success of the hypermedia design to develop knowledge and cognitive flexibility, variables related to knowledge acquisition, concept development, cognitive re-structuring, and problem solving must be examined.

3.3 Software Audit Trail

The computer program contains a complete data collection system to capture usage data and learning outcomes through an audit trail (Misanchuk & Schwier, 1992). The datapath for the user provides a continuous record of the user's sequence through the various components and activities and time spent in each component. The written records entered into the computer problem-solving activities are stored in separate files on floppy disks.

4 Participants in the Study

Subjects were twenty-three preservice teachers enrolled in a methods course in behavioral disorders. All students had completed foundational coursework in special education and had substantial prior knowledge upon which they began to develop specialized knowledge in the area of behavioral disorders. Demographic information for the participants served as independent variables.

Prior Computer Experience

Almost all participants had experience using computers for general productivity tool uses, particularly word processing. Most students had never experienced hypermedia programs and only two students responded that they had "some knowledge" of hypermedia. Based on a scale where students rated their experience from 0 = "no knowledge" to 9 = "expert knowledge" on 9 categories of computer applications (total score possible = 81), the mean prior experience score = 25, standard deviation = 10.78, range = 5 to 43.

Rank in School

The participants included 17 seniors and 6 post-bacculaeareate/graduate students.

Learning Styles

Participants represented a mix of field independence and field dependence as measured by their scores on the Group Embedded Figures Test (Witkin, Oltman, Rashkin, & Karp, 1971). Using quartile scores to segment the participants into learning style groups, 4 participants were classified as field dependents (FD), 11 as field dependents mixed (FDM), 5 as field independents mixed (FIM), and 3 as field independents (FI).

5 Data Collection for Dependent Variables

Data were collected prior to use of the hypermedia program (pre) and following completion of the last case study (post). A *knowledge test* consisting of 25 multiple choice questions was constructed from test banks available for two of the primary textbooks used in the field. The content of the information base contained within the hypermedia program was consistent with the content of the textbooks and the knowledge test.

Each student constructed a *concept map* prior to use of the hypermedia program (pre) and following completion of the last case study (post). The maps displayed how each student would organize his or her approach to understanding a child with a behavioral disorder. The concept maps were constructed during supervised class time within a 30-minute time frame without the use of notes or advanced notice of the activity. Each concept map was scored for (a) number of unique concept nodes, (b) number of links between nodes, and (c) number of levels constructed in the concept maps.

Path analysis data were collected from records stored on user floppy disks. Data collected from the audit trail included (a) total time spent on each of the case studies, (b) total time spent in each of the program choices, (c) the number of times each program choice was accessed, (d) results of an on-line quiz embedded within each case study, and (e) electronic responses to all on-line problem-solving activities included within the case studies.

6 Data Analysis and Results

6.1 Outcomes Related to Prior Experience with Computers

Simple regressions were run to evaluate whether outcomes of hypermedia-based instruction were related to differing levels of prior experience with computers. Table 1 presents the regression results for four dependent outcome variables: a) knowledge test, b) number of unique concept nodes on concept maps, c) number of links on concept maps, and d) number of levels included in concept maps. Regressions were run for pre as well as post outcome scores. No significant relationships were found to indicate that prior computer experience was related to differences in pre-treatment scores. Similarly, no significant relationships were found to indicate that prior computer experience predicted learning outcomes based on hypermediated instruction.

	Pre Treatment			Post Treatment		
	r	*F*-value	*p*	*r*	*F*-value	p
Knowledge score	.129	.357	.557	.164	.357	.557
Number of unique concept nodes	.060	.976	.786	.060	1.544	.228
Number of links	.156	.523	.477	.020	.523	.477
Number of levels	.146	.460	.505	.029	.018	.896

Table 1. Outcomes for Students Blocked by Prior Experience with Computers

6.2 Outcomes Related to Student Rank in School

To evaluate whether hypermedia-based instruction affected the learning outcomes of preservice teachers with different levels of higher education, four dependent measures were examined for users blocked into two groups: undergraduate students and graduate/post-baccalaureate students. Table 1 presents the results for two-factor ANOVAs for the dependent variables: a) knowledge test, b) number of unique nodes on concept maps, c) number of links on concept maps, and d) number of levels on the concept maps. Results are included for the group (rank) and outcome (pre/post) main effects. Findings revealed no significant differences in learning outcomes using the hypermedia program which were related to student rank in school.

	Undergraduate Post Mean	Graduate Post Mean	Rank *F*-value	*p*	Pre/Post *t*-value	p
Knowledge score	18.88	18.17	.639	.434	106.147	.001 *
Number of unique nodes	48.24	52.50	1.291	.269	9.870	.005 *
Number of links	54.77	66.17	3.610	.070	9.470	.006 *
Number of levels	4.77	4.67	.820	.375	.266	.611

Table 2. Learning Outcomes for Students Blocked by Rank in School

6.3 Outcomes Related to Learning Styles

To evaluate whether hypermedia-based instruction affected the learning outcomes of preservice teachers with different levels of field independence/dependence, four dependent measures were examined for users blocked into four groups: first quartile (field independents - FI), second quartile (field independents mixed- FIM), third quartile (field dependents mixed - FDM), and fourth quartile (field dependents - FD). Two-factor ANOVAs with one within (pre and post) and one between (field independence/dependence) factor were used to analyze differences. Table 3 presents the results of the two-factor ANOVAs for the dependent variables: a) knowledge test, b) number of unique nodes on the concept maps, c) number of links on the concept maps, and d) number of levels on the concept maps. Results are included for the group (learning style) and outcome (pre/post) main effects.

Findings revealed no significant differences on learning outcomes using the hypermedia program that were related to differences in learning style depicted through field independence and field dependence. There were no significant main effects for the group variable. Significant pre-to-post differences were found for knowledge score (p =.0001), number of unique nodes on concept maps (p =.003), and number of links on concepts maps (p =.004). No significant difference was found for the fourth dependent variable, the number of levels contained in the concept maps (p. =.636).

Post-Scores	FD Mean	FDM Mean	FIM Mean	FI Mean	Learning Style *F*-Value	*p*	Pre/Post *F*-Value	p
Knowledge score	18.75	18.91	18.40	18.33	1.272	.312	152.850	<.001 *
Number of unique nodes	42.50	48.55	57.80	47.33	1.429	.265	11.521	.003 *
Number of links	50.50	59.00	64.20	52.00	1.000	.414	11.103	.004 *
Number of levels	6.50	4.36	4.80	3.67	2.364	.103	.232	.636

Table 3. Learning Outcomes for Students Blocked by Field Independence/Dependence

7 Audit Trail Analysis of Field Dependent and Field Independent Learners

The audit trail records of six students were examined for differences in usage patterns of the hypermedia program. Three students whose scores fell in the first quartile on available norms for the Group Embedded Figures Test were classified as field dependents (FD); three students whose scores fell in the fourth quartile were classified as field independents (FI) (Witkin et al, 1971).

7.1 Total Engagement Time

FI users spent 7.27 hours engaged in the two case studies compared to 7.19 hours for FD users. This difference was not statistically significant based on an unpaired t-test analysis (t = .-46, p = .96). These results indicate that users with different levels of field independence/dependence engaged in the hypermedia program an equivalent amount of time for learning.

7.2 Internal Jumps to Access Information

An analysis was done comparing the number of program choices selected in the final case study by gathering frequency data on button clicking. FI users made more selections with an average of 128 program selections compared to FD users who made an average of 91 selections. This difference was not statistically significant based on an unpaired t-test analysis (t = -.88, p =.429). These results indicate that users with different levels of field independence/dependence utilized options in the program with similar frequencies.

7.3 Proportional Engagement in Instructional Components

Table 4 displays the proportion of usage time the students engaged in the instructional components of the hypermedia program. Using an unpaired t-test analysis, differences between the FI and the FD users were not significant for seeking information and watching videos; but differences were highly significant for listening to experts and engagement in on-line problem-solving activities. Results indicated that users with different levels of field independence/dependence utilized the hypermedia program in different ways.

Instructional Component	Proportion of Time Mean for FD	Proportion of Time Mean for FI	*t* (4)	*p*
Seeking Procedural and Case Information	41.59	48.56	-2.015	.114
Watching Videos of Children	8.52	12.95	-1.359	.246
Listening to Expert Commentary	7.19	15.85	-8.038	.001 *
Doing On-line Problem-solving Activities	41.38	22.54	3.651	.021 *

Table 4. Proportion of Time Users Engaged in Instructional Components

7.4 On-line Quiz Scores

The on-line quiz scores for the case studies were averaged for each user based on the second-attempt score. Second attempts were used instead of first attempts because most users looked at the quiz before making a serious attempt to achieve the criterion score (80%) established by the instructor. FI users achieved an average of 76.7% compared to 73.3% for FD users. This difference was not significant based on an unpaired t-test analysis (t = -.447, p =.678). These results indicate that users with different levels of field independence/dependence demonstrated equivalent levels of achievement on the quizzes embedded within the hypermedia program.

7.5 On-line Problem-solving Reports

Two scores were derived from on-line reports written as a part of the problem-solving activities in the program. (1) A personal perspectives score rated responses to the on-line question prompts: *What is your perspective of this child's needs?* and *How do you support this position?* (2) A team synthesis score rated responses to the question prompts: *Who would you like to be on the team for this child?* and *What views do your team members share?*

Responses were scored by the two researchers using a holistic scoring rubric and differences were resolved prior to data analysis. On the *personal perspectives* comparison, no significant difference was found between users with different levels of field independence/dependence. Using a paired t-test analysis, the mean difference was 0.7 on a five-point scale ($t = -.417$; $p = .698$). Similarly, no significant difference was found on the *team synthesis* comparison between users with different levels of field independence/dependence. The mean difference was 0.33 on a five-point scale ($t = .25$; $p = .815$).

Similarity of scores indicated the users were equally successful in solving the case study simulations requiring them to develop personal perspectives toward children with behavioral problems, select therapeutic team members, and synthesize shared goals and beliefs across the team members.

8 Discussion

The findings from this study support the belief that hypermedia *is* good for instruction. College-age adult learners who utilized the extensive hypermedia environment demonstrated that they *could* and *would* customize their use of the program. Differences among the learners were documented by three variables—rank in school, prior experiences using computers, and learning style as expressed in field independence/dependence. Given the significant growth in knowledge as demonstrated on the pre/post knowledge test and the increased breadth and complexity of knowledge construction as demonstrated through the concept mapping procedure, it appears that the hypermedia learning environment provided equally effective instruction for learners regardless of their differences.

To examine how field dependent and field independent learners actually utilized the hypermedia program, audit trail records for six users were examined. Although these users spent equivalent amounts of time engaged in the program and demonstrated similar patterns of information access, significant differences were found in their choices within the instructional components of the program. Regardless of these usage differences, performance in on-line quizzes and problem-solving activities was similar.

In summary, users with differing learning profiles and usage patterns were equally successful in knowledge construction. These conclusions may be limited to a robust hypermedia intervention which is effectively integrated into an appropriate instructional program and conducted over a sufficiently long treatment period.

JAVA CONCEPT MAPS FOR THE LEARNING WEB

Roberto A. Flores-Méndez
Knowledge Science Institute
University of Calgary
Alberta, Canada T2N 1N4
robertof@cpsc.ucalgary.ca

Abstract: Concept maps are graphical representations used for organizing and communicating knowledge. In conjunction with computer mediated communication, concept maps can be used to support distributed collaboration workgroups on the Internet and the World Wide Web (the *Web*). However, the diversity of computer platforms conforming the Internet makes desirable the implementation of portable applications to avoid discriminating computer platforms or overworking on diverging versions for multiple operating systems. This paper describes the implementation of jKSImapper and jKSImapplet, which are portable Java concept mapping tools used as instruments for supporting workgroup collaboration on the Internet and the Web.

1. INTRODUCTION.

The learning web [Norrie & Gaines 1995], was envisioned as part of a learning society where individuals are submerged in a life-lasting process of acquiring knowledge for coping with evolving environments. Individuals will not longer succeed in isolation or with a fixed amount of knowledge, but rather operate as part of integrated collaborative workgroups, where digital networks will be used for communication and collaboration [Shaw & Gaines 1996].

Under this scheme, tools are required for supporting the communication and sharing of knowledge, and for transmitting that knowledge to each member of a community. Computer mediated communication has been very effective in empowering human intelligence, resulting on the selection of digital computers and networks as the appropriate transmission media.

This paper will address the implementation of a portable concept mapping tool as a support for workgroup knowledge sharing on a learning environment, having the Internet as the transmission infrastructure, and Java as a viable solution for providing cross-platform execution of code among the diversity of computer architectures found on the Internet.

2. CONCEPT MAPS.

One of the mechanisms for organizing and communicating knowledge among individuals are concept maps [Gaines & Shaw 1995a]. Concept maps encompass a wide variety of diagrammatic knowledge representations. They can be defined as diagrams composed of links and nodes of different types. Concept maps can graphically represent and organize arguments and thoughts, thus providing an alternative to natural languages as a means to communicate knowledge.

[Fig. 1] shows a concept map constructed to visualize features found in the Java programming language. In this figure circular nodes were used to represent concepts, rectangular nodes to represent specific instances, and labeled arrows to represent relationships.

2.1. APPLICATIONS.

Concept maps have been applied on areas ranging from education [Novak & Gowin, 1984] and management [Axelrod 1976] to artificial intelligence [Quillian 1968] and knowledge acquisition [McNeese, Zaff, Peio, Snyder, Duncan & McFarren 1990]. Even when some of these disciplines may require specific constraints (also called *formalisms*) for interpreting and organizing information, the developments described on this paper do not enforce any of them.

Figure 1: Concept map on the Java language.

Scenarios where concept maps can be used as a groupware tool include:

- ***Brainstorming:*** Where known concepts and relationships are suggested by individuals for conforming a meaningful workgroup knowledge structure.
- ***Decision making:*** Where current variables are identified on existent knowledge structures, leading to logical inferences that, ultimately, will help for decision making.
- ***Information navigation:*** Where concept maps are used as hypermedia organizers. In this case, information can be encapsulated on different levels of abstraction for easy comprehension, while allowing expansion to reveal details when required.
- ***Presentation planning:*** Where concept maps are used as tools for outlining content in a non-linear manner. This technique allows a quick interpretation of related material and their relationship with the subject of the presentation.

3. PORTABLE CONCEPT MAPPING TOOLS FOR THE INTERNET AND THE WORLD WIDE WEB.

While concept mapping systems are a valuable tool for the single user, their potential is fully achieved in multi-user environments. On such environments, concept mapping tools can provide a user interface to shared resources, and can support a range of group processes such as brainstorming and join development of knowledge structures [Kremer & Gaines 1994]. The use of a networking environment is required for supporting timely and geographically dispersed communities. From existing computer networks, the Internet presents the most suitable environment for multi-user applications, due to its wide extension and vast number of users. Additionally, hypermedia is supported on the Internet by the means of the World Wide Web.

BEST COPY AVAILABLE

Previous developments at the Knowledge Science Institute have also addressed the need for supporting concept mapping tools on the Web. Such developments were successfully integrated as helper applications and Netscape plug-ins under the Macintosh, MS-Windows and Unix operating systems [Gaines & Shaw 1995b] [Kremer 1996] [Lapsley 1995]. Unfortunately, such tools implement dissimilar user interfaces, and often produce concept mapping data that is incompatible between computer platforms.

3.1. PORTABILITY.

The existence of many computer architectures integrated to the Internet demands a viable solution for cross-platform execution of code. In other words, programs need to be constructed with characteristics that allow their execution on many computer platforms, without modification. Programs with such ability are called portable or cross-platform.

Portable code can be classified into two categories depending on the transformation that the source code receives:

- ***Scripted code***: No transformation at all; source code is transmitted unmodified for the receptor to validate, interpret and execute. Known scripting programming languages on the Web include Tcl/Tk [Ousterhout 1994], JavaScript [Netscape 1995] and Python [van Rossum 1996].
- ***Intermediate code***: Source code is compiled, at development time, to a specific set of instructions "generalized" for execution on diverse computer architectures. The modified code will be interpreted when transmitted to receptors. The Java programming language [Sun 1996] is an example of intermediate code.

4. JKSIMAPPER AND JKSIMAPPLET.

jKSImapper and jKSImapplet are systems designed to support multi-user asynchronous concept mapping elicitation on the Internet and the World Wide Web. These systems were entirely implemented using the Java programming language, and were developed based on the Java *jCMap* class library. This library can be extended for implementing concept mapping systems that enforce formal knowledge constraints, such as Conceptual Graphs [Sowa, 1984].

4.1. THE JCMAP CLASS HIERARCHY.

Previous projects at the Knowledge Science Institute have produced a class hierarchy suitable for implementing an open-architecture concept mapping system. This class hierarchy, which is known as *CMap* [KSI 1996], was constructed using the C++ programming language. The aim of this hierarchy was to isolate the functionality of a concept mapping application from representations inherent to specific operating environments, thus improving source code portability.

[Fig. 2] shows the Java jCMap class hierarchy, which is derived from the CMap class hierarchy. This figure, which was created using jKSImapper, contains different visual elements for representing entities, inheritance and runtime relationships. Rectangular nodes were used to represent classes; ellipse nodes, for depicting interfaces; shaded nodes, for showing abstraction on classes and interfaces (which are abstract by default); and non-shaded nodes, for representing instanceable classes. Links also carry different meanings. Non-labeled links are used for representing inheritance, and labeled links are used for showing association between objects at runtime.

4.2. RUNTIME SYSTEM ARCHITECTURE.

The systems described on this work were designed as client/server applications. jKSImapper and jKSImapplet perform as client programs that interact with a server process. While client systems are designed to perform as elicitation agents for constructing concept maps, server processes are planed as central coordinators of elicitation sessions and as data repositories.

4.2.1. CLIENT SYSTEMS.

Concept mapping client systems developed from the jCMap class library can be executed as Java applets or as Java standalone applications. As explained next, the differences between applets and applications are evident on the context of their use:

- Java applets are programs downloaded from remote servers and executed locally by Web browsers. This process is automatically performed each time an applet is encountered during Web navigation. The execution of Java applets requires browsers with a built-in Java Runtime Interpreter.
- Java applications are also programs, but they do not require the presence of a Web browser for downloading or execution. In that sense, Java applications are like any other regular standalone program that users may choose to install on their computer. Java applications require a Java Runtime Interpreter installed on the client computer.

[Fig. 3] shows a jKSImapper standalone application and a jKSImapplet applet running inside an instance of Netscape's Navigator. In this example, both programs collaborate for constructing a conceptual graph describing the sentence "No student read the book the teacher wrote," which is contained on a remote session maintained by a server process.

Figure 3: Groupware Concept Mapping Collaboration using jKSImapper and jKSImapplet.

jKSImapplet and jKSImapper are both aimed to the construction of concept maps. However, these programs hold slight differences on their implementation, specially on the user interface and the storage of data. jKSImapper implements menu options and can save concept mapping data either on the local disk or on remote servers. On the other hand, jKSImapplet does not implement menus and does not allow to save data locally. Applets do not implement menus since they do not own a window context (it belongs to the Web browser). Additionally, applets are not allowed to use certain client resources (such as secondary storage) due to security reasons. As shown on [Fig. 3], menus on jKSImapplet were replaced by widgets embedded on the Web document containing the applet. These widgets are designed to use JavaScript for triggering methods on jKSImapplet, thus effectively satisfying the need for menus. In the case of saving concept mapping data, jKSImapplet just allows storage on the server process to which it is connected.

4.2.2. SERVER PROCESS.

The jKSImapper Server is a process executed by server computers. This program has been designed to receive and maintain networking connections with client concept mapping programs, and to support multiple multi-user concept mapping elicitation sessions. Server processes are able to store concept mapping data on secondary storage.

Clients connected to a server process can send and receive commands generated as part of a concept mapping elicitation session. Such commands are stored by the server process on the history list of the session where the client is currently active. Commands are then broadcast to all the participants in the session (including the sender) for execution.

Figure 4: jKSImapplet Execution Structure.

[Fig. 4] and [Fig. 5] show the execution structure for jKSImapplet and jKSImapper, respectively. jKSImapplet is an applet that performs inside Web browsers. During Web navigation, browsers routinely download HTML documents containing links to hypermedia resources. In the case of jKSImapplet, when browsers detect the applet linked to a Web document, they will use their embedded Java interpreter for obtaining the corresponding classes from the server. Once downloaded, the classes will be used for executing the applet. After initialization, jKSImapplet will request a communication channel to the server for engaging on a multi-user concept mapping elicitation session. The applet will have access to secondary storage on the server for saving concept mapping data.

jKSImapper
jKSImapper Server
Client Computer
Server Computer

Figure 5: jKSImapper Execution Structure.

On the other hand, jKSImapper is a standalone application. Differently from jKSImapplet, jKSimapper classes are located on the client computer, and they do not require a Web browser for execution. However, a Java interpreter is still needed for running the program. Once invoked, the interpreter will load and execute the classes corresponding to the program. After initialization, jKSImapper may or may not request a connection to a server process for engaging to a remote session. Such session can be shared with other jKSImapper and jKSImapplet programs. If a networking connection is not requested, jKSImapper will work on its own single-user elicitation session. jKSImapper applications can access disk storage on client and remote server computers.

5. CONCLUSION.

Concept maps are a valuable tool for supporting visual thought processes. This characteristic has been reflected in the development of computer-based tools to represent concept maps graphically. The increasing availability of shared resources on the Internet and the Web, and the development of portable programming languages, such as Java, have opened new possibilities for distributed real-time collaboration. This paper has described the implementation of the jKSImapper and jKSImapplet multi-user concept mapping systems. These developments, which are fully operational as groupware tools for the Internet and the World Wide Web, can provide effective support for many significant conceptual processes in the learning web.

Abstract: This paper reports on the development of Webmaker, a tool for the conceptualisation, structuring and delivery of educational materials via the world wide web (WWW). The paper identifies the need for the tool, describes its functionality and indicates its potential for further development.

1.0 The Need for Such a Tool

The increase in the use of the Internet not only as a repository of resources for learning but also as a means for the delivery of courses and specially prepared teaching material over the last two years is a particularly significant innovation in the range of educational provision. One site for example, that of the Internet University claims to list over 700 courses available over the internet [URL 1 1997]. Specialist courses which can no longer be supported by drawing on the student base in the traditional university catchment area can now be offered economically world wide[URL 2 1997]. But of equal significance is the way that the WWW is being incorporated into course provision within "conventional" campus based institutions. De Montfort University in the UK is typical in this regard. Various course elements are provided for student access via the WWW in a number of Faculties and major plans are underway to offer many more. These rapid developments have significant consequences:

- Faculty staff who are subject specialists in their own discipline area are becoming involved in web based delivery with little or no experience of developing materials for this medium;
- Faculty staff may find themselves working as part of a project team containing a range of specialists including courseware designers, programmers and graphics specialists. New and effective working relationships need to be developed so that the specific contribution of each member can be efficiently incorporated into the team as a whole;
- Materials developed for delivery via conventional printed means may be "repackaged" for delivery via the web with little or no adaptation of their structure for the changed medium.

But to produce successful web based courseware needs more than simply marking up existing material for use on the web; like all educational enterprises there is a need for careful planning and structuring. The collaborative process of courseware development also requires management tools - a need not yet addressed by most existing web creation tools.

2.0 Current Development Tools

A range of tools is now available to assist with courseware development and delivery. These are classified into three main groups below in order to indicate their relation to WebMaker.

Design and Mark-up tools such as HomePage (Claris) or Pagemill (Adobe) speed up the creation of web pages without the need to enter Hypertext Markup Language (HTML) code directly. However such packages primarily assist in the *design* of individual pages and do not assist with issues relating to the *structure* of the project as a whole. Webmaker is not designed to compete with such tools but to compliment them.

Assessment tools such as Questionmark[URL 3 1997] and FLAX [URL 4 1997] enable the incorporation of a wide range of assessment styles and methods into web based courses and this is of central importance in an educational context. Webmaker does not duplicate such functionality but facilitates its' appropriate incorporation within the structure of the courseware.

Web Courseware Management Systems can be broadly classified into two groups.

- WEST[URL 5 1997] for example, provide integrated solutions for courseware on the WWW by providing tutors with a mechanism for placing material, giving them a framework in which to produce certain forms of assessment activities, delivering e-mail based tuition and student monitoring and record keeping features. Students are provided with a complimentary environment in which they study the materials thereby providing a complete course delivery environment. Such systems have much to offer but they are primarily delivery vehicles rather than tools to assist in courseware creation.

- Other systems such as STILE [URL 6 1997] offer tools for the management of resources for teaching and learning. Staff can make available a wide range of resources which can be classified, searched and accessed in a variety of ways.

Recently Downes has cautioned against any over-reliance on complete management systems.
The really truly hard part to web-based course design is in content design. Any reasonably competent computer professional can provide chat facilities, threaded discussion lists, web pages, on-line registration, etc. But the core of on-line course materials will have to be determined by experts in the field working with experts in distance education delivery. [Downes, 1997]

We believe that this process can be facilitated through the use of tools such Webmaker.

3.0 The Importance of Concept Mapping

We have argued previously [Freeman and Ryan, 1995] that courseware is best developed in a team context, whereby individuals with a range of skills (subject experts, instructional designers, programmers) work together to agreed aims and objectives in the development of a project.

The development of powerful web authoring tools, and tools for the conversion of word processed documents into HTML format can tend to encourage the collapse of these various roles into one person - the universal courseware expert. When using such tools there is a tendency not to map out the courseware first, but in the act of marking up, to try to structure it at the same time. In effect, what happens is that the producer is both attempting to structure and plan the courseware and produce it simultaneously and in the process of so doing may lose sight of the main pedagogic and structures and navigational routes.

Courseware on the web may have a number of additional features not normally found in stand alone computer based packages. As well as the core sequence and structure of the material, whereby the user will proceed via a menu, next or previous buttons, clicking on an image map or some other navigational devices, typically it will contain hypertext links to other pages or to information held on other WWW sites. For example, definitions of terms, references, additional material or links. These may be explored by the student before returning to the main sequence of the courseware. These additional features mean that an overall planning and structuring of the educational project is critical in order to reduce the possibilities of the student becoming "lost in cyberspace" at worst or at best wasting time and effort following secondary links of little or marginal relevance. It is therefore important to spend time conceptualising the total project and considering what links (if any) have primacy.

Webmaker is a tool of two parts. The first part an icon based concept mapping tool, developed from previous tools we have used for the development of stand alone multimedia projects. It allows a subject expert working alone or, where appropriate, an instructional designer, to map out and plan the entire courseware project before that courseware is created. Using the system the developer may, via the manipulation of icons, try out the different links and routes, add and delete proposed sections and run through various sequences without being concerned about the actual delivery. This encourages the top level planning of the entire courseware prior to any attempt to construct it. The act of planning and structuring is therefore separated from the production. The second part of the tool is the Linker, which converts the map into HTML ready for use on the WWW.

3.1 Integrating Planning and Development

If a map of ideas alone were being provided, this could be done on paper or by using a commercially available package. Part of the planning process is to consider how the ideas mapped out will be realised and delivered via various media and how features of media can best be used for teaching purposes. Therefore, as part of the conceptualisation, it is necessary to specify how, for example, graphics, text, video or sound will be used and incorporated in to the delivery system.

At the mapping stage Webmaker provides a way of indicating the way in which media and content will be integrated within the final structure. This information developed at the concept mapping stage serves as a template for others to build and implement in the delivery system. Other parts of the package enable prototypes to be built and tested.

3.2 Team Roles

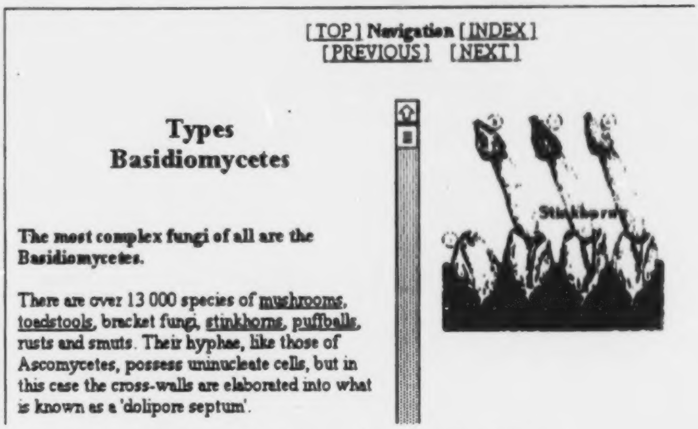
These tools provide ways in which each team member can clearly define their own role and at the same time locate that contribution within the overall structure. Because the concept mapping software and associated documentation is available to all course team members it greatly facilitates project management. For example, the graphic designer may examine the concept map to understand the context of a request by the map's author for an image.The designer can then supply an appropriate image rather than a generic one.

Most importantly this process is documented. At any time print-outs can be obtained showing the latest version of the map, details of all links plus any additional instructions or messages from one member of the team to another. In this way project planning and management are greatly facilitated.

4 Webmaker: an Overview

The application consists of two functional units each with several distinct parts:
- Knowledge structuring, which includes a concept mapping tool, a documentary library and a hierarchy builder,
- Preparation and production of HTML, which includes a resource linker, and an HTML generator.

To start we will describe the output from the application - the HTML file as seen by the end user in a WWW browser. [Figure 1] shows the browser view of an HTML output file. This is prior to any customisation in a web page design tool. Three frames are present. The top frame contains navigation information, particularly 'next' and 'previous' links; the left-hand frame contains text with embedded hypertext links, whilst the right-hand frame contains an image. Now consider the view at the concept mapping stage: [Figure 2]. Notice the sequence of four nodes - "phycomycetes", "ascomycetes", "basidiomycet" and "imperfecti".



[TOP] **Navigation** [INDEX]
[PREVIOUS] [NEXT]

Types
Basidiomycetes

The most complex fungi of all are the Basidiomycetes.

There are over 13 000 species of mushrooms, toadstools, bracket fungi, stinkhorns, puffballs, rusts and smuts. Their hyphae, like those of Ascomycetes, possess uninucleate cells, but in this case the cross-walls are elaborated into what is known as a 'dolipore septum'.

Figure 1: the browser view of an html output

By defining these four nodes as a sequence in the conceptmapping component, their relationship is maintained through to the WWW browser view. Note also that some of the text in the browser is active and results in the appearance of different images or other resources in the right-hand frame of the browser.

4.1 The Concept Map

The concept map begins as a blank window in which nodes are created, deleted, repositioned and linked. Figure 2 shows a small map. At this point the main concerns are the structure and relationships at the map level and the textual content of the nodes. Double-clicking on a node opens a node window into which text may be entered.

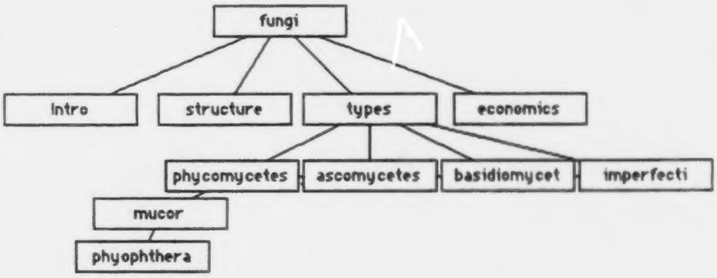


Figure 2: the concept mapping stage

Two processes occur here: text entry and the assignment of activity to a word or phrase in the text. Any word hilited and surrounded by square brackets indicates that a *description* exists for the type of activity or resource associated with it in the final WWW document. However, the resource is not produced at this point: it is produced later by other members of the team. Resources may of several types, such as a GIF, a sound (RealAudio or QuickTime), another node (i.e. another WWW document contained within the concept map or another WWW site), PDF document, JAVA applet, or Shockwave plug-in. The nature of the resource is passed on to the other team members through the documentation feature of the application.

4.1.1 Branching

In the map, [Figure 2], the node "phycomycetes" must be a branch node because there are more than two

BEST COPY AVAILABLE

destinations from it. The hierarchy building component of the application is used to describe the branching structure of the subject domain described by the map.

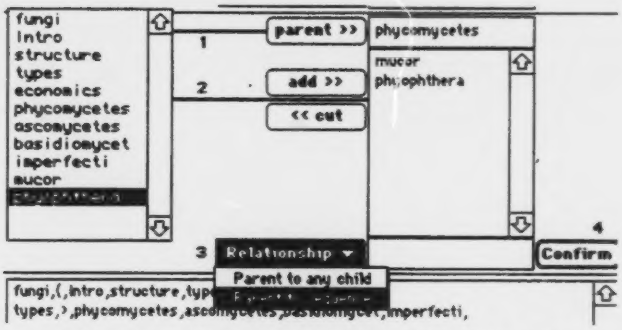

Figure 3: node hierarchy being built (part of image)

Figure 3 shows a hierarchy being built, in this case from the parent node "phycomycetes" to its siblings, "mucor" and "phytophthera". The relationship between the parent and siblings is identified at point 3, and the sequential nature of the linking is enforced by the navigational structure in the WWW page. Alternatively, the relationship "Parent to any child" might be selected. In this case the navigational space would include the names of all of the nodes, giving the user free choice.

4.1.2 Preparing the Map for the Web

So far the map consists of textual content and a branching structure: the GIF, FLAX, JAVA, RealAudio and other resources do not yet exist. An export from the map of all text and notes for resources is now passed to the graphic design members of the team so that requirements for resources may be stated within the context of the subject. The linkage of requirement to resource can be completed once the resources have been delivered, using the "Link Builder" window, [Figure 4]. Here active text such as the word "stinkhorns" is linked to a physical resource, the GIF image canis.GIF. Linkage can only occur if the resource is available. Similarly, the puffballs link is allocated to a WWW address.

The form of the browser window for this node is chosen using the controls at the bottom of the window. The browser may consist of a single window ("full") or a variation on a framed structure. Navigation information always appears in the top frame. The placement of the textual component is chosen by the radio buttons on the right.

4.2 Documentation from the Concept Map

A key aim was to provide tools not only to develop courseware but also to manage and document the process: The major documentation tools are described below.

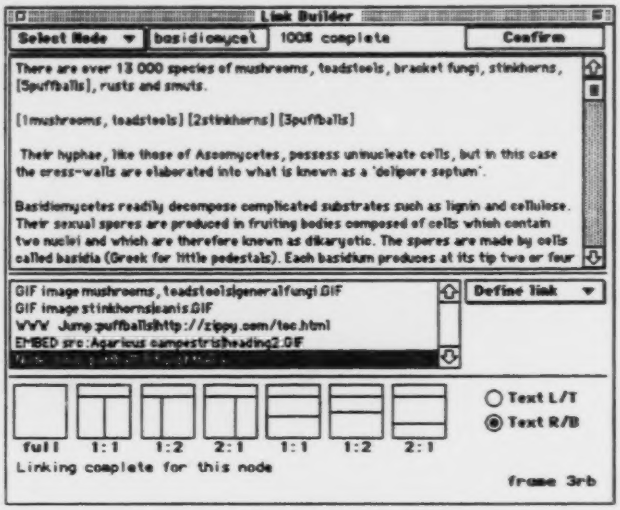
- Notes are for annotation of the map and can be placed anywhere on it.
- The documentary window provides an overview of the entire process of development, recording saves, the number of nodes, node creation, deletion and linkage. It is in effect a history of the entire development.
- The node summary provides an overview of all the resource elements of each node such as text, graphics or hypertext links. Its main use is to provide an overview of the entire structure and can be exported to an ASCII file for incorporation into other project documentation, or printed out.

4.3 HTML Generation

Compilation to HTML takes less than 5 minutes even for very large or complex maps and has no visible component except for a dialogue box showing an indicator bar. The process will compile all fully-linked nodes.

BEST COPY AVAILABLE

so even one node may be built if necessary. Error reporting is full, and is included within the documentation that is stored with the project. The compiled output from the editor is saved as HTML documents which vary in size from 120 bytes to 4Kb, depending on the complexity of the frame. These documents may then be further modified using any html editing tools or made available directly to students.



There are over 13 000 species of mushrooms, toadstools, bracket fungi, stinkhorns, [5puffballs], rusts and smuts.

[1mushrooms, toadstools] [2stinkhorns] [3puffballs]

Their hyphae, like those of Ascomycetes, possess uninucleate cells, but in this case the cross-walls are elaborated into what is known as a 'dolipore septum'.

Basidiomycetes readily decompose complicated substrates such as lignin and cellulose. Their sexual spores are produced in fruiting bodies composed of cells which contain two nuclei and which are therefore known as dikaryotic. The spores are made by cells called basidia (Greek for little pedestals). Each basidium produces at its tip two or four

GIF image mushrooms, toadstools|generalfungi.GIF
GIF image stinkhorns|canis.GIF
WWW Jump:puffballs|http://zippy.com/toc.html
EMBED src:Agaricus campestris|heading2.GIF

Linking complete for this node

Figure 4: the "Link Builder" window

One important component of this stage is the generation of a textual equivalent of the concept map. Rather than build a graphical representation in a web-browser window of what might be a very large map a decision was taken to use a familiar and easier structure - an indented contents listing. The contents listing may be edited so that spelling and case may be altered. A single click on a subject brings a sample of the text from that HTML document into the other frame of the browser. Another click takes the user to the full information.

Conclusion

The impact of the world wide web as a means of course delivery is now huge. Many academics are experimenting by putting up their courses on the web sometimes, by themselves or as part of a project team. It is essential that the entire courseware project is structured prior to development and that appropriate tools are available to assist in this process, and to provide detailed project planning and management support. Webmaker is a contribution to this need.

A Repository-based Approach to Reuse of Educational System Resources

Takashi Fuji
Software Research Laboratory
45 Nishinopporo, Ebetsu-shi, Hokkaido 069 Japan
E-mail: fuji@srl.co.jp

Abstract: This paper describes a methodology for educational systems development, and the educational systems development environment called REBECCA. The methodology, which is based on information engineering, is used to support navigation for courseware development and educational system resources management. A repository-based approach is key to support of educational systems development and reuse of educational system resources such as application frameworks and components.

By the structure of the repository such as meta-model / model / object base and by use of object-oriented modeling, REBECCA is constructed for ease of reuse by systems analysts and subject matter experts. Systems analysts can build new models by reusing meta-models and models for their target system. Subject matter experts can develop their courseware by reusing models and object bases for their educational systems.

Introduction

Educational systems based on instructional design theory [Merrill 1987; Gagné 1993; Tennyson & Breuer 1993] are becoming a major interest. Systems such as ID Expert [Merrill 1987], IDE [Russell et al. 1988], GAIDA [Gagné 1993] and CREAM [Nkambou et al. 1996] have been developed by instructional design automation. These systems provide a set of tools to be used in the instructional process. However, these systems do not have a mechanism for reuse of educational system resources such as application frameworks and pedagogy components. These systems are constructed mainly for reuse of instructional units and for curriculum conception.

Software reuse, a subject of long-standing interest, has recently emerged in a new, business-critical guise. Software reuse is effective to achieve the goal of a software organization, which is to build useful working software systems in time and within given economic constraints. In particular, application frameworks and components based on object-oriented technology are the main reusable elements in reuse projects such as REBOOT [Karlsson 1995].

We have developed two kinds of application frameworks, AVALON [Fuji et al. 1994] for the individual learning environment and CAMELOT [Fuji et al. 1995b; Fuji et al. 1996] for the collaborative learning environment. These application frameworks are built by use of object-oriented technology, and are stored in the REBECCA repository system [Fuji et al. 1995a] for reuse. Repository-based methodology is derived from information engineering [Martin 1989] and instructional design theory.

The purpose of this paper is to present the methodology and development environment (which is called REBECCA) for a systems analyst and a subject matter expert according to the object-oriented repository approach. For a systems analyst, REBECCA enables the reconstruction of educational systems by reusing application frameworks such as AVALON and CAMELOT. For a subject matter expert, REBECCA provides a means of course navigation, the reuse of pedagogies and instructional units, and target system generation.

This paper is organized into three sections. Section 2 outlines the methodology. Section 3 introduces the basic concepts of REBECCA. Section 4 describes the architecture of REBECCA.

Methodology for Educational Systems Development with Repository

In software engineering, structured techniques are applied to one project, whereas in information engineering, structured techniques are applied to the enterprise as a whole or to a large sector of the enterprise. Information engineering techniques encompass those of software engineering in a modified form [Martin 1989]. Information engineering has been defined with reference to automated techniques as follows: an interlocking set of automated techniques in which enterprise models, data models and process models are built up in a repository and are used to create and maintain data-processing systems. The repository is one of key technologies in information engineering, and it steadily accumulates information relating to the planning, analysis, design, construction and, later, the maintenance of systems.

The field of instructional design was initiated by the United States Department of Defense during World War II to improve the efficiency of certain types of high-level technical training programs such as pilot training [Reiser, 1987]. The systems approach is a step-by-step procedure for solving problems. It has been applied to educational problems at all levels, from education as a whole, to training for a specific target population. In instructional design, the systems approach is sometimes referred to as instructional systems development (ISD). There are numerous models of this approach. Although the models differ in detail, such as the number and sequence of steps or the way in which specific components are grouped, the steps are grouped into the following five categories: analysis, design, production, implementation, and evaluation.

The methodology of REBECCA (Repository-based Environment for Computerized Courseware Analysis) is based those of information engineering and instructional design. The characteristics of this methodology are as follows.

- Object-oriented repository for managing educational system resources
- Reuse for educational systems framework
  (individual learning environment / collaborative learning environment)
- Reuse for educational systems components
  (instructional object / pedagogy object)
- Instructional objects for individual adaptive learning
  (multimedia object / knowledge object)
- Navigation for courseware development (analysis, design, construction)

The Basic Concepts of REBECCA

Managing Educational System Resources

Educational system resources are stored in the repository and reused through the repository. The major functions of educational system resource management are as follows.

Conceptual modeling

This function is used by systems analysts. When an educational system is to be developed, educational systems frameworks such as AVALON and CAMELOT are used to create a skeleton of an educational system. Systems analysts modify the skeleton by reusing frameworks, and REBECCA supports a construction of a conceptual model using the object modeling technique [Rumbaugh et al.1991]. As a meta-model, an object model is used.

Consistency management

Educational system resources in the repository are necessary to keep consistency for the object. If systems analysts modify the frameworks using symbols which are not defined in the meta-model, the system checks the consistency between the meta-model and the frameworks.

Browsing repository

By means of the browsing function, the user can view the contents of the repository. Systems analysts can view the structure of the repository, and subject matter experts can view the reusable frameworks and components.

Supporting the Function for Educational Systems Development

Navigation for courseware development

The steps of educational systems development are analysis, design, and construction. Subject matter experts define the learning environment, and specify a learning goal and theme in the analysis phase. In the design phase, they specify reusable educational resources, such as pedagogy object and instructional object. They can locate the reusable resources by using the thesaurus. In the construction phase, they produce the instructional object which cannot be reused, and finally, the system generates the target educational system required by the subject matter expert. The system navigates these procedures based on the methodology. Figure 1 shows the process flow of educational systems development for the subject matter expert.

Designing the course

The subject matter expert can reuse the curriculum stored in the repository, and add new themes or delete unnecessary themes. At the same time, he or she can retrieve instructional objects related to the theme by using the thesaurus. This thesaurus has been developed for information systems education in universities.

Designing the curriculum with collaboration

In defining the curriculum, especially in new domains such as information systems education, collaboration is useful. REBECCA supports collaborative work on the Internet using a discussion model in order to define a new curriculum. Using the WWW, subject matter experts from various countries can define a curriculum while sharing ideas. The defined curriculum database is stored in a WWW Server. Figure 2 shows a sample screen for designing a curriculum.

Architecture of REBECCA

Structure of Repository

A repository is a place for storing all the information required in a software engineering environment, for example tools, software products and documents. The PCTE, Portable Common Tool Environment, is a standard for a public tool interface for an open repository [Wakeman & Jowett 1993]. However a meta-model of the PCTE is defined by extended Entity-Relationship modeling and is not defined encapsulation. The meta-model of REBECCA is defined by an object model.

CDIF, the Case Data Interchange Format, has been developed to define the structure and content of a transfer that may be used to exchange data between two CASE tools. CDIF uses models to define the information content of transfer. Several layers of model are used; the second being an abstraction of the first, the third of the second, and so on [CDIF Technical Committee 1994]. The structure of a repository is based on the CDIF architecture. The repository of REBECCA is composed of three levels. Figure 3 shows the structure and functionality of the repository.

Figure 3: Structure and functionality of the repository

Level 1: Meta-model

The first level holds a model of about level 2, i.e. a model about the model describing the resources at level 3. Models about models are commonly called meta-models. The semantic content of the meta-model is defined using notations of object modeling techniques, such as class, association, generalization, aggregation. This meta-model also self-describes the repository.

Level 2: Model

The second level in the repository is the conceptual model defined using the meta-model. Frameworks and components are described in the model. AVALON, the framework for an individual learning environment, functions as a multimedia intelligent tutoring system. CAMELOT is the framework for the collaborative learning environment. The instructional object and pedagogy object are components that can be reused.

Level 3: Object Base

The third level in the repository is the implemented objects based on the level 2 model. There are executable educational systems, development tools, and instructional resources.

A Framework for Educational Systems

The reuse approach relies on the concept of reusable software components produced and stored in a repository. There are two main types of object-oriented components: solution-based inheritance hierarchies and domain-based frameworks [Karlson 1995]. This framework is based on domain-based frameworks such as educational systems. The educational systems frameworks used are AVALON for the individual learning environment and CAMELOT for collaborative learning.

AVALON

The AVALON educational system framework is a multimedia intelligent tutoring system. The system provides adaptive instructional units and pedagogy suited to the learners' understanding. The system also provides multimedia instructional units, such as video, voice, text, and image data, suited to the learners' characteristics.

CAMELOT

The CAMELOT educational system framework is a collaborative learning support system. The learning process is based on a nominal group technique. The system facilitates collaborative learning navigation, group discussion, and remedy of collaborative work solutions. The pedagogy is a combination of rule-based reasoning and case-based reasoning.

Components for Educational Systems Development

Instructional object

An instructional object is an extended instructional unit. An instructional object is composed of a multimedia object and a knowledge object. A multimedia object incorporates multimedia instructional material, such as text, image, voice, and video. A knowledge object incorporates the knowledge representation of instructional units, such as semantic network, rule-based reasoning, and case-based reasoning. An instructional object is used for components when subject matter experts design courseware.

Pedagogy object

The basic concept of the pedagogy object is based on Gagné's accumulated learning model [Gagné 1985]. Pedagogy objects are composed of "problem solving", "rule learning", "concept learning", "multiple discrimination learning", "verbal association", "chaining", "stimulus-response learning", and "signal learning". Subject matter experts can design their pedagogy for educational systems by combining these pedagogy objects.

Conclusions

In this paper, I have described a methodology for educational systems development, and the educational systems development environment called REBECCA. The repository approach is key to supporting educational systems development and reusing educational system resources such as application frameworks and components. Using three-level structure, such as meta-model/model/object base, and using object-oriented modeling, REBECCA is constructed for ease of reuse for systems analysts and subject matter experts.

In line with the widespread use of the Internet, I believe that the reuse of educational resources on the Internet is becoming an important technical issue. The project is currently addressing the subsequent phase of a distributed developing environment with CORBA.

Abstract: It is recognized that increasing costs and the convergence of computer and communications technologies are creating pressures on universities to transform their modes of operation to be more appropriate to modern society. This article analyzes the transformation of educational institutions from a *learning web* perspective, detailing the critical drivers, obstacles and resources for transformation, and proposing some specific modes of operation for a networked higher educational system. It concludes with a section on how the learning web may be implemented by increasing the flexibility and reducing the cost of university administration through electronic commerce systems.

1 Transforming Educational Institutions

In their influential study on *Transforming Higher Education* for the Society for College and University Planning (SCUP), Dolence and Norris (1995) note that:

> *The Information Age is an epoch where "higher education" could occupy the pivotal role in society. It is a time when demand for learning is anticipated to skyrocket, but resources available under existing models for educational delivery are expected to remain fairly static. Fresh vision is needed to create new delivery systems for learning, new paradigms for financing, and new models for higher education.*

The vision of a *learning web* has been proposed as a model for a future learning society in which individuals, organizations, computational agents and services, and other resources are linked through digital networks to function in a variety of self-organizing, goal-directed systems (Norrie and Gaines, 1995b). Experiments in the application of the learning web to undergraduate collaborative learning have been reported (Shaw and Gaines, 1996), as have the development of special-purpose tools supporting the learning processes in the web (Gaines and Shaw, 1995; Shaw and Gaines, 1995).

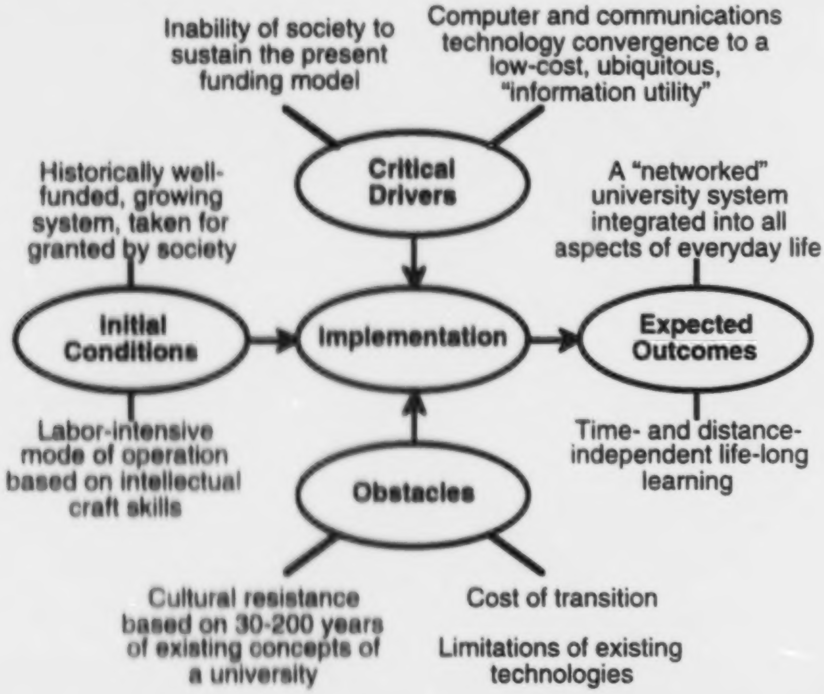
An article at EdMedia'96 addressed the rationale for, and systemic foundations of, the learning web, its implications for restructuring the higher education system, and the role of information technology in supporting that restructuring (Gaines, Norrie and Shaw, 1996). This article analyzes the transformation of educational institutions from a learning web perspective, detailing the critical drivers, obstacles and resources for transformation, and proposing some specific modes of operation for a networked higher educational system.

2 The Dynamics of Transformation

In analyzing social change one specifies the initial conditions, the expected outcomes, the critical drivers for change, the expected obstacles to change, and then considers the implementation of change in the light of these factors. Figure 1 diagrams this analysis for the higher educational system.

The initial conditions are that our current universities are a historically well-funded, growing system, taken for granted by society, but their mode of operation is labor-intensive and based on intellectual craft skills. The drivers for change are the inability of society to sustain the present funding model (Clotfelter, Ehrenberg, Getz and Siegfried, 1991; Clotfelter, 1996), and the convergence of computer and communications to a low-cost ubiquitous 'information utility' (Martin, 1978; Gaines, 1996). The obstacles to change are our existing cultures based on 30-200 years of existing concepts of a university, the cost of funding the transition, and the limitations of existing technologies.

An expected outcome is a networked world-wide university system integrated into all aspects of everyday life which will support time- and distance-independent life-long learning (Rossman, 1992; Harasim, Hiltz, Teles and Turoff, 1995). The logic behind this predicted outcome will emerge as we consider the resources required to implement changes that will make universities more cost-effective in fulfilling their roles in society.



Inability of society to sustain the present funding model
Computer and communications technology convergence to a low-cost, ubiquitous, "information utility"
Critical Drivers
Historically well-funded, growing system, taken for granted by society
A "networked" university system integrated into all aspects of everyday life
Initial Conditions
Implementation
Expected Outcomes
Labor-intensive mode of operation based on intellectual craft skills
Obstacles
Time- and distance-independent life-long learning
Cultural resistance based on 30-200 years of existing concepts of a university
Cost of transition
Limitations of existing technologies

Figure 1 Factors in the transition to a post-modern university system

I have used the much-abused term "post-modern" to describe the networked university because of its connotations of a post-industrial, post-regimented, post-authoritarian age, where people at large recognize that human meaning and human culture are human inventions that are their choice and their responsibility (Aronowitz and Giroux, 1991; Lyotard, 1992). The authority of the academy is being undermined now in the post-modern enlightenment in the same way that the authority of the church was undermined 300 years ago in the modern enlightenment (Schmidt, 1996). Universities cannot stand aside from society as the ultimate conservators, guardians and disseminators of knowledge. They have to become an integral part of a world community where digital communications and media are becoming commonplace, and the students of North America will converse with the people of France or Japan or Russia across the Internet as readily as they chat to their neighbors.

3 The Resources for Transformation

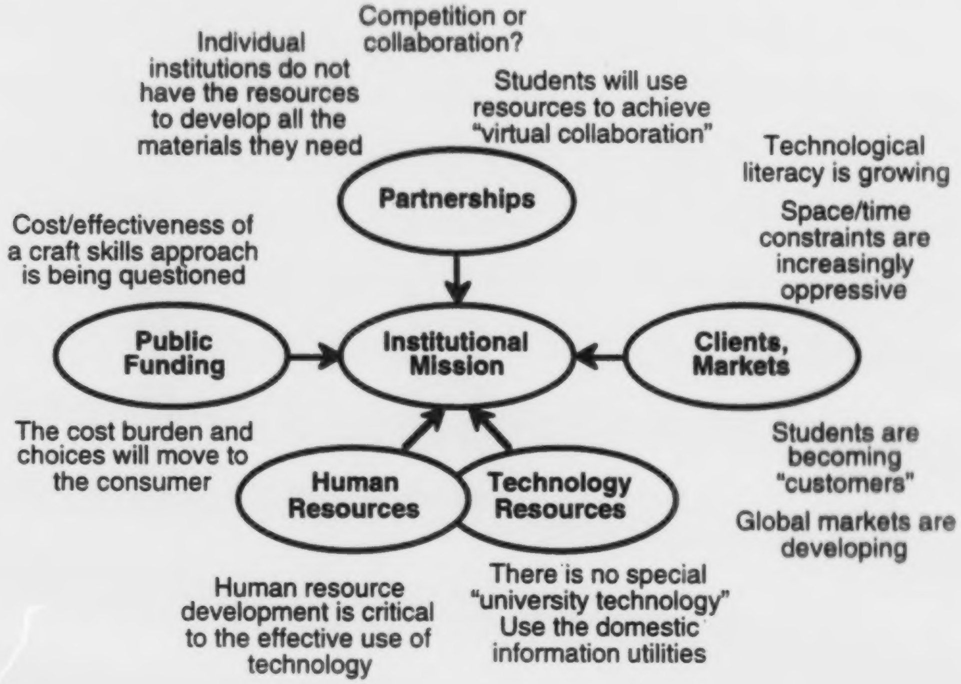
If universities are to transform, both the outcome and the dynamics of transformation are critically dependent on the resource structure that supports them. Figure 2 presents a graphical analysis of the major resources involved. At the center is the definition of the institutional mission. It may seem strange to treat this as a resource, but the existence of a well-defined mission statement, accepted by all the major participants is a key resource in managing change. It is salutary to read Newman's introduction in 1852 to his Dublin lectures on *The Idea of a University*, and recognize that in every age the idea of a university has been brought into question (Turner, 1996). Newman states:

> *The view taken of a University in these Discourses is the following:- That it is a place of* teaching *universal* knowledge. *This implies that its object is, on the one hand, intellectual, not moral; and, on the other, that it is the diffusion and extension of knowledge rather than the advancement. If its objects were scientific and philosophical discovery, I do not see why a University should have students; if religious training, I do not see how it can be the seat of literature and science."*

If one took out the adjective "religious" qualifying training, then this statement of a century and a half ago could be seen as a contribution to the current debates on the roles of the university in research, teaching and training.

Underlying most mission statements is the notion of the university as a *community of scholarship*, where scholarship is some form of open, critical inquiry expressed as overt knowledge. Newman's notion of universal knowledge is suspect in a post-modern world where all knowledge is seen as a human construct subject to a variety of human biases. However, universality does not imply absolutism, and the objective of universality in the sense of being shareable throughout a world-wide community is still at the heart of the notion of scholarship. Landow (1996) in his essay on *Newman and the Idea of an Electronic University* emphasizes the support of collegiality possible through electronic networks, "an idea more honored in the breach than in the observance" in our existing physical institutions.

The mission of the university system as a whole may be defined in terms of a community of scholarship, but the mission statements of particular universities have to go beyond this in defining their particular intended contributions to that community. In the past, a particular physical location could be a major component of the mission—many universities were formed to serve their local communities on the assumption that it was most cost-effective for students to enroll at a university close to their homes. That assumption is now coming into question as digital communications support the possibility of a virtual university, accessed electronically rather than physically. However, the idealized notion of a community of scholars does not address all the reasons why a student might wish to attend a university. University education is only one component of the life experience of individuals and many other factors may determine the attractiveness of a particular university. Those other factors need to be made explicit in a mission statement. In addition, there may be aspects of the scholarly experience in terms of involvement in human society and culture that the technology does not yet support well, and those aspects need to be made explicit in a mission statement if the role of the technology is to be properly evaluable. Overall, in times of change, it becomes very important to be explicit, comprehensive and correct in defining the institutional mission.



Competition or collaboration?
Individual institutions do not have the resources to develop all the materials they need
Students will use resources to achieve "virtual collaboration"
Technological literacy is growing
Space/time constraints are increasingly oppressive
Partnerships
Cost/effectiveness of a craft skills approach is being questioned
Public Funding
Institutional Mission
Clients, Markets
The cost burden and choices will move to the consumer
Students are becoming "customers"
Global markets are developing
Human Resources
Technology Resources
Human resource development is critical to the effective use of technology
There is no special "university technology" Use the domestic information utilities

Figure 2 Resources involved in the transition

On the left of Figure 2 are the resources supplied to universities through the general social levies of public funding. These resources are reducing because the cost-effectiveness of universities is seen as suspect, and a free market economy in which resources are allocated according to value received is seen as more appropriate. On the right, resources from this free market are shown where students as customers are increasingly technologically literate and find the space and time constraints of having to attend a particular location at a prescribed time increasingly oppressive. In addition, the true clients who provide the funding may be the employers of the students, making workplace education significant, and global markets are developing for higher education services world-wide.

The internal resources for change are still in large part people—as much, if not greater, effort needs to be put into developing human resources as into technical ones. The provision of technology resources is becoming increasingly simple as domestic information utilities gain the high speed multimedia and discourse support facilities necessary for effective knowledge dissemination. If universities need to develop a specialist 'technology' of their own it is at the intellectual level of facilitating learning through the effective use of the commonly available information technologies.

The most significant resource issue is that shown at the top of Figure 2, the development of *partnerships* because individual institutions do not have the resources to develop all the materials they need. One response to the availability of distance-independent higher education may be to compete in the physical territories of other universities, and in the short-term this is happening for expensive professional qualifications. However, in the longer term those competing in this way will find their positions eroded as other institutions join the competition and drive prices down so that the distance education market becomes fragmented and financially less attractive. The natural economic model is one of virtual collaboration through market differentiation in which different institutions specialize in the provision of different higher educational services. Students will take course modules from different institutions and be accredited for their qualifications by other institutions that may specialize in accreditation and management of the learning process rather than content provision.

It is these considerations that lead to the expected outcome of a *networked university system integrated into all aspects of everyday life* as shown on the right of Figure 1. They do not lead to a monolithic model in which all higher education is in the cyberspace of a completely virtual university. People have an existence in the physical world also, and different university locations, their amenities and cultures will still be relevant to where students reside. It is an intrinsic feature of the growth of lifelong learning that more students will be concerned about the location of their employment also, but with tele-commuting a growing trend the decision as to whether to telecommute for ones education or ones employment, or both, will be an increasingly open option. The "network" will not be purely electronic but will involve the heterogeneous integration of learning experiences in the physical classroom, workplace, and virtual campuses of many educational institutions.

4 Learning Web Administration through Electronic Commerce

The pedagogical principles underlying the implementation of the learning web have already been analyzed (Norrie and Gaines, 1995a; Gaines et al., 1996) and exemplars given (Gaines and Shaw, 1996; Shaw and Gaines, 1996; Herlea, Shaw and Gaines, 1997; Shaw and Gaines, 1997). They stem from the basic concept of a learning society as an autopoietic system recursively structured as a network of intelligent learning agents, with the agents ranging from major social complexes and institutions through to roles in individuals (Gaines, 1994). The emphasis on structured social networks leads to pedagogical principles that facilitate the formation of social learning environments where students are resources for one another and where instructors are more facilitators than lecturers.

However, the development of networked higher education resources raises as many administrative issues as it does pedagogical ones. Implementing a distributed social learning environment involves the management of a heterogeneous mixture of resources from many sources. In terms of existing systems it may be seen as requiring the *modularization* of courses to generate a wide range of *virtual courses* tailored to learner needs. The use of modules from various sources to constitute an accreditable virtual course is educationally attractive in providing greater variety for students with different learning styles. It also makes it easier for faculty to specialize in the provision of modules in which they have specialist knowledge both of content and appropriate learning environments and teaching styles.

The administration of virtual courses within a virtual university presents major problems. Universities already have a cumbersome and expensive bureaucracy to deal with the administrative and financial transactions of large numbers of students taking individual mixes of courses on different time scales. Some aspects of administration, such as room allocation and class scheduling will become much simpler for time- and distance-independent learning. However, the current system is complex already in coping with the charging for courses and in the allocation of the resulting resources to the units responsible for courses. Modularization and outsourcing of course modules will increase the administrative complexity by an order of magnitude and require new systems for charging for comparatively small transactions with a low overhead in transaction costs.

This is precisely the problem being addressed by new developments in electronic commerce where customers shop in electronic malls on the Internet and the entire transaction from product browsing, through ordering and payment, to delivery is automated. The efficiency of the banks EDI systems is now such that transactions resulting in payments of less than $1 can now be carried out cost-effectively. A good example is MIX, the ManGlobe International eXchange (http://www.manglobe.com/index2.htm) which provides the backend services for retailers offering products on the web in collaboration with the Royal Bank of Canada.

A MIX retailer pays the cost of operating a web site together with a transaction fee of 5% with a maximum of $10 to ManGlobe for taking care of the administrative and financial aspects of the transaction including credit clearance, inventory management, delivery tracking and payment. An additional 1.5% is levied if ManGlobe handles a credit card transaction on behalf of the retailer. The ManGlobe technology is designed to ensure transaction security through the issue of confidential identifiers to customers that control access to their financial sources.

This model is directly applicable to the provision of learning modules as retail products through the web. It provides for the comparatively small financial transactions involved with a low administrative overhead and detailed tracking. Inventory management is relevant where modules have an associated human component such as email access to an instructor and it is important to control the numbers of students enrolled at the same time. The secure transaction technology provides the beginnings of a system for checking that a student being assessed is the one actually registered for the module, although that is a more complex problem than ensuring the security of a financial transaction.

An electronic commerce model of a higher education shopping mall may not seem attractive, or appropriate, to many academics, but it takes care of the administrative operation of a university that most of them do not perceive. From a pedagogical perspective, the issue will be one of developing educational modules that can be delivered effectively through the various means available, not only the web, but also through classes, seminars, self-study modules not on the web, and so on. The overall learning environment will be one of *team teaching* with the team extending to colleagues at a range of other institutions. It is often said that the administrative aspects of a university are a major influence in stifling innovation in the exploration of new teaching techniques and learning environments. The provision of a highly flexible and cost-effective administrative system through electronic commerce techniques could remove the major impediments to innovations in teaching and learning.

5 Conclusions

It is recognized that increasing costs and the convergence of computer and communications technologies are creating pressures on universities to transform their modes of operation to be more appropriate to modern society. This article has analyzed the transformation of educational institutions from a learning web perspective, detailing the critical drivers, obstacles and resources for transformation, and proposing some specific modes of operation for a networked higher educational system. It has suggested how the learning web may be implemented by increasing the flexibility and reducing the cost of university administration through electronic commerce systems.

The transformation of universities into a world-wide networked higher educational system that is responsive to the needs of post-modern society and the opportunities offered by the convergence of information technologies requires changes in many aspects of the operation of the university, not only in the teaching methodologies and learning environments but also in the adminstrative infrastructure. None of these changes affects the university system's fundamental role in society in supporting a community of scholarship providing open, critical inquiry into all aspects of our existence. The changes are in the way in which that role is carried out and in the opening of the community to transcend physical and other boundaries. The task of the scholar today is to preserve the integrity of the scholarly process while taking full advantages of technologies which extend the collegial domain to any person in any location world-wide.

Abstract: This paper presents HYPERCLINIC, a cooperative hypermedia system to support medical students with diagnostic learning and the planning of cardiologic therapeutic procedures. HYPERCLINIC provides an integrated environment for patient record manipulation, including images, sounds and graphics. The system has facilities for individual and group learning as well as desktop conferences between cardiologists physicians and students in Intranet environments.
The system was implemented at the Cardiology and Cardiovascular Surgery Unit of UFBA/Fundação Bahiana de Cardiologia in cooperation with the Department of Computer Science of COPPE/UFRJ.

1. Introduction

Medical practice is an essentially cooperative activity. Due to the constantly increasing complexity of the tasks to be accomplished, the association of physicians to find more efficient solutions to health problems becomes more and more important. In university and specialized hospitals, such cooperation plays a vital role in the formation of a good health care professional.
Besides that, medicine increasingly leans upon technological resources which are broadly applied, both in teaching and in the medical practice, influencing either directly or indirectly the health service professional's work. Within this context, research is developing hypermedia cooperative systems [Ng et al. 93], [Kleinholz & Ohly 94], [Cheng et al. 95] to support cooperation among physicians involved in situations in which information sharing is important. Examples are the process of diagnosis or when you have to decide for the procedure which has to be applied in a particular case.
HYPERCLINIC is a cooperative hypermedia system designed to the medical education of cardiologists. Its main purpose is to support medical sessions where medical students and specialists interact in order to analyze complex clinical cases. The clinical session works as a class in which the students exercise their diagnosis ability through the analysis of problems related to the field of study.
The HYPERCLINIC system has been developed and evaluated at the Cardiology and Cardiovascular Surgery Unit (UCCV) of UFBa's Professor Edgar Santos University Hospital in association with Bahia's Cardiology Foundation (FBC) and the Department of Computer Science of COPPE-Federal University of Rio de Janeiro.

2. Medical Education

Conventional medical instruction faces several problems related to the changes in the educational process involving social aspects that affect the classroom culture, the concept of continuous education and technological questions. Barnett [Barnett 95] lists some of these problems:

- the poor emphasis that medicine colleges place on the importance of continuous education;
- the difficulty with knowledge maintenance due to the information explosion relative to the amount and complexity of the new scientific knowledge, which is vital to medical science, and also to the fast pace at which new ailment diagnosis and treatment methods are developing;
- the use of an educational strategy for the transmission of medical knowledge that is eminently passive, the student being left in such a position that he/she is merely a receptor, which is not suitable to medical instruction;
- the difficult integration of the theoretical material learned during the first years of academic life into the clinical training given at the end of the medical course. Moreover, the syllabuses of the various subjects sometimes lack integration with each other, making it hard to approach the solutions to practical clinical problems coherently.

The solution to those problems depend on changes to be made both in the curricula and in the priorities of medical schools. As a result, information technology can be seen as a long term solution. As computer science is incorporated in the educational process, bringing along mechanisms to simplify, discipline and improve the expression of reasoning, the quality of educational models, strategies and contents also improves, fitting education for the new reality of a modern world [Campos 94]. In recent years, there has been significant progress in the development of new medical educational systems, such as simulators [Woolf & Hall 95], tutorials [Lee et al. 94], [Pavel 95], conferencing systems [Ng et al. 93], [Kleinholz & Ohly 94] and systems designed for the study of medical cases [Kaltenbach 94], [Cheng et al. 95].

2.1 Learner-Centered Education

The new, learner-centered approach is based upon the idea that people learn best when they are concerned with the subject in question, because they feel motivated to search for a new understanding and develop skills so as to be able to solve real problems. The focus of attention lies on the student's *needs*, *abilities*, and *interests*. This kind of teaching-learning process usually appears in association with a problem-solving approach, the problems being chosen so as to meet the students needs. The major goal is to center the instruction in a set of realistic, intrinsically motivating problems [Norman & Spohrer 96], [Soloway & Pryor 96]. Hence, the active exploration and build-up of learning are strongly stimulated.

In the core of such changes lie the new technologies, which appear as powerful tools that allow the application of several construtivist ideas [Schank et al. 95], [Norman & Spohrer 96].

2.2 Hypermedia Systems

Hypermedia systems have a great potential of applicability in training and education in both scientific and non-scientific fields [Nielsen 90]. Whenever multimedia technology is inserted in an adequate educational context it inspires active learning by favoring an exploratory attitude towards the subject of study. The information is presented in a concrete form that is easy to grasp. Moreover, it provides the student with constant feedback, allowing him to take part in the instructional process.

The kind of information used by health care professionals in the treatment of a patient are essentially multimedia [Kleinholz & Ohly 94], [Dayhoff 93], [Ip et al. 93]. The information backing a diagnosis comes from different sources and appears in different forms, such as reports, graphs, diagrams, references to books, handwritten notes, films, video tape sequences, audio tapes and conversations with patients and colleagues [Kleinnholz & Ohly 94]. Therefore, much of clinical investigation and medical diagnosis relies on the interpretation of visual data [Ratib 93], [Klingler et al. 92].

In Cardiology, the interpretation of images, charts and sounds is crucial in an adequate therapeutical guidance. A computerized educational system to be used in the study of clinical cases, capable of integrating such information and using the hypermedia resources in a unique environment adds a significant contribution to the learning process. Furthermore, if the project of the educational software joins together multimedia resources and other technologies, such as artificial intelligence [Woolf & Hall 95] and cooperative work, it is capable of supporting a high quality, effective learning.

2.3 Computer-Supported Cooperative Work

Since the learning process involves the evaluation of facts, principles or procedures, the definition and solving of problems, and creativity, students need interpersonal communication along with the opportunity to question, defend and discuss matters. Therefore, the educational process can be regarded as a social rather than an individual activity [Bates 94].

The explosive growth of computer networks, mainly after the popularization of Internet and the WWW (World Wide Web) technology, greatly increased the possibilities to spread computer-supported cooperative activities.

Medicine is a natural area of application for distributed, collaborative multimedia systems. Hypermedia conferencing systems are particularly attractive to promote the cooperation among physicians [Ng et al. 93]. The use of conferencing tools, integrated with the applications which access and handle the patients data, results in a faster, more precise diagnosis, increases the information availability, and brings forth new opportunities to consult specialists [Kleinholz & Ohly 94].

3. The Cardiology Clinical Session

The purpose of the Cardiology Clinical Session at UCCV/FBC is to help the medical students to develop the ability to make the interpretation of clinical cases of different pathologies. The study of cases involves the handling of information from the patient's record, made up of text, graphs, images and video tapes.

In the course of the session, real clinical cases involving patients admitted to the university hospital are discussed by cardiologists, resident physicians and students. This meeting defines the therapeutic procedure to be applied in each case.

During the medical session, resident physicians deepen and set in their knowledge. It also gives them an opportunity to express their opinions on real, complex cases and come to final decisions, thus improving their interpretative capabilities. To the students, the session offers the opportunity to get a better knowledge of the specialties of cardiology and the diagnosis techniques applied in this field, as well as to see how the theoretical concepts learned throughout the medical course work in practice.

There are specific stages in the clinical session, ranging from the selection of the case to be discussed up to the final decision about the therapeutic method to follow. The stages are described bellow:

a) Selecting case, information gathering and organization of the data: Because of its educational character, the clinical session begins with the presentation of cases by the students, under the supervision of physicians. The physicians select the more interesting cases, which are either emergencies or current complications in the clinical situation. Resident physicians, along with the students, gather and organize the information and then present the summary of the case, according with the due clinical methods .

b) Review of the cases and students preparation: A few days before the session, a student gives his colleagues and supervising physician a preview, so as to consolidate his presentation and review the relevant points concerning the case. The physician leads the group in the interpretation of the results obtained in medical examinations and eventually discusses the therapeutic procedure to be applied and makes suggestions for further reading.

c) Presentation of cases: When the clinical session begins, clinical and interventionist cardiologists, Cardiology residents, medical students, heart and thorax surgeons, and perhaps some invited professors, are present. The meeting is coordinated by the head of the Cardiology and Cardiovascular Surgery Unit.

Every case is presented by a student and by those physicians who represent the sub-units which made the examinations involving images, such as the echocardiogram and the catheterism.

After the presentation, the session coordinator begins the discussion, asking the intern who is responsible for the case to present a summary of it, as well as a suggested therapeutical conduct that he/she will justify. Afterwards, the physicians argue the case, demonstrate weak points and define the therapeutic procedure that is to be applied. The coordinator arises discussions and collate competing opinions so as to show the possibilities and shortcomings of the treatment options. References to the medical literature and to well established cardiology standards can be used to justify opinions. At the end of the discussion, the coordinator summarizes the therapeutical conduct to be followed.

4. Hyperclinic System

Taking the approach of learner-centered teaching as a basis, an active learning environment to be used in medical studies has been designed which supports the study of clinical cases in Cardiology, as well as the basic research and the interaction among the students.

The HYPERCLINIC system allows students in different stages of knowledge to view complex cases and to interact with instructors, physicians and other colleagues. The system's assumption is that the discussions and the access to clinical and bibliographical data should make it easier for the student to design a diagnosis and to define therapeutical procedures. In doing so, the student learns through exploration, stimulating the development of creativeness and mental organization in the construction of knowledge.

HYPERCLINIC shows characteristics of computer supported cooperative work and includes the highly desirable possibility of cooperation among the students accomplished through the information exchange, group study and the supervision of a preceptor. The system is available through the Intranet in several sites at the Cardiology and Cardiovascular Surgery Unit, making the access and the interaction among users very easy. Thus, each student may study at a different place, whenever it is more convenient to him at his own pace. He can redo the tasks as many times as necessary and interacting with colleagues and/or instructors any time he wants.

Such a program uses tools which support the process of organizing, preparing an presenting the selected cases for the clinical sessions. It also keeps a database that keeps records of all the cases already studied for further reference so that cases with similar pathologies can be checked out for similar solutions. Moreover, it can access bibliographical and tutorial cardiology databases designed at UCCV/FBC [Pavel 95], [Aragón et al. 95].

The system can also enlarge the clinical session objectives, introducing a further stage of study that allow cardiologists and students to follow a continuous education program. Such program uses the possibility to access the cases through the Web network or through a CD-ROM, including the video of the session debate, which shows the procedure followed to determine the adequate therapeutical conduct.

4.1 System Architecture

The Hyperclinic system makes use of the Web Architecture. The user's workstation, running a Web browser and plug-ins for multimedia data, accesses a local Web Server, which offers a number of options for patient case study or inclusion of new cases. Common Gateway Interfaces (CGI) programs on the Web Server access the Database Server to generate Hypertext Markup Language (HTML) documents [Fig. 1].

Hyperclinic has three distinct environments: Authoring, Study, and Presentation Environment.

a) Authoring Environment: This environment gathers the clinical cases. Firstly, forms which contain the information related to the patient must be filled in. The conventional data, images and video sequences from examinations are captured or recovered from other systems to build up the patient's case. All the pieces of information concerning the patient are stored in a multimedia database.

b) Study Environment: Using a WWW browser the students analyze the cases, having the chance to do research, add notes, make diagnosis, give suggestions of therapeutic procedures, and interact with instructors and colleagues.

c) Presentation Environment: This module allows the visualization of clinical cases, serving as an integrated means of presentation to be used during the session. It replaces all other audiovisual media, such as the overhead projector and the VCR. The conclusions drawn from each case in the session are included for further study.

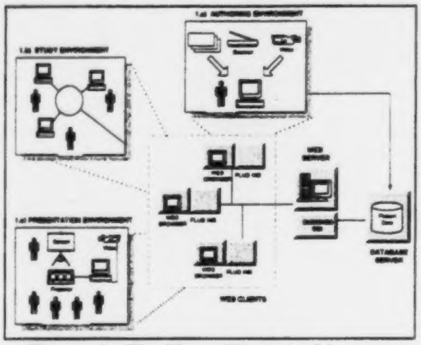

Figure 1 - The HyperClinic Architecture

4.2 Cooperation Mechanisms

Amongst the various possibilities of mechanisms to support both synchronous and asynchronous communication and cooperation those which could contribute to the achievement of the systems objectives have been selected. The list given bellow describes such mechanisms and the way in which their incorporation to Hyperclinic have been accomplished.

Group structuring by definition of roles and related privileges in the manipulation of clinical cases. The roles and privileges which have been defined in the system are:

- Student - is allowed to examine the clinical cases, make research, add notes, suggest diagnosis and therapeutic procedures and includes questions in the List of Doubts;
- Preceptor - responsible for students tuition; checks out what students have already studied a particular patient's case, whether they have added a comment or not and what their doubts are, if there is any. He is also allowed to add entries to the glossary of terms and answers to questions appearing in the List of Doubts;
- Physician - examine the cases, gives opinions on the cases and answers questions appearing in the List of Doubts;
- Technical Administrator - manages the list of system users (includes, deletes or changes user's data), defines privileges, includes data concerning new cases and updates system information, such as dates of events, the medical sessions schedule, messages, etc.

Aid to the generation of ideas and use of the community suggestion board. Hyperclinic system has the following mechanisms:

- List of Doubts - a session containing the most commonly asked questions of students and the answers given by the physicians and/or the preceptor;
- Bulletin Board - may be used to display a number of varied pieces of information, such as calls for academic works presentation, notices about conferences, meetings, lectures, etc.

Support to several types of communication (both formal and informal):

- Electronic mail;
- On-line conferencing - a site for discussions where physicians, preceptors and students can interact simultaneously, exchange information about the cases and cooperate to define a joint diagnosis or therapeutic procedure suited for a particular case.

Mechanism to make the "presence" of the group members at a given time more apparent. In the literature this is referred to as "group consciousness".

- List of Active Users - displays a list showing all the users that are connected to the system at that time.

4.3 Study and Research Mechanisms

Support of the information access, through "navigation" instruments and structured queries accomplished by the browser itself or provided by the application.

- Aid to navigation - the student can have an overview of the case under study, so as to determine which parts of the document have already been examined. This prevents the student to get "lost" within the hyperdocument;
- Selection of cases based upon a list of attributes (e.g.: the patient's name, diagnosis, date of clinical session, etc.);
- Functions performed by Web browsers: printing of documents, inclusion of notes, bookmarks, etc.

Support to research:

- Glossary of Medical Terms, specific for Cardiology - this glossary can be changed by physicians and instructors, who can add more information to it;
- Access to tutorials specifically designed to deal with subjects related to Cardiology.

5. Conclusions

This paper presents the HYPERCLINIC, a system designed to support the teaching/learning process in Cardiology, using a learner-centered, case-based approach. The system offers an environment suitable for the preparation, study and presentation of cardiology clinical sessions, providing tools to accomplish group study and the sharing of multimedia information.

With the aid of this system, students can interact more frequently with colleagues and instructors and the clinical cases can be studied in a more structured way, taking advantage of the hypermedia environment. Due to students cooperation, the learning process becomes easier and the rate of transmission of knowledge increases.

The prospects for the future include the access to the system through the Internet. Students could then accomplish broader research works, accessing bibliographical bases distributed by the net and taking part in discussion forums and conferences. A further goal is to add mechanisms to support teleconferencing, so that physicians of other hospitals could be virtual participants in the clinical session, thus allowing the creation of multicenter groups of study.

A running prototype has been developed which uses an Intranet environment to achieve easy of use and future transparency between Intranet and Internet environments.

Cooperative Learning: Students As IT Experts And Resource Personnel In The Classrooms

Siowck-Lee Gan
Institute for Distance Education
Universiti Pertanian Malaysia
gansl@pppl.upm.edu.my

Abstract: This paper reports on how pre-planned, structured cooperative learning activities centered around the computer and the Internet are used to effect interaction and solve some of the teaching-learning problems in the classrooms of Malaysian secondary schools. Specifically, these activities have been structured with the at-risk students playing the lead role of IT experts who work closely with the teachers and their groupmates to source for useful materials for teaching-learning activities in the classroom. Preliminary findings from the study have found that such interesting learning experiences with CD-ROM multimedia reference materials and the Internet, plus the prestigious role as IT experts and resource personnel in the classroom, have had very positive effect on the at-risk students.

Introduction

Since the early days of computer-based instruction (CBI) there has always been an emphasis on individualized instruction which focuses on self-pacing and the prescription of instructional methods and materials according to learner individual goals and needs. The rationale for individualization in computer-based instruction is so appealing that most computer-based learning materials have been designed for that purpose. However, despite the emphasis on matching instruction to individual learners, in reality, students often have to work at the computers in small groups, simply because most schools are unable to provide one-to-one computing facility.

Research in cooperative learning in the last two decades has consistently pointed to important instructional and affective benefits. With regard to CBI, in addition to improving achievement, cooperative learning methods may actually provide a cost-efficient way of using the computers. For example, if students were to work in groups of two or more, hardware costs can be reduced by at least 50%! More importantly, cooperative learning that focuses on interaction may also be a solution to the problem of social isolation associated with individual CBI activities. [Rysavy & Sales 1991] reviewed research in recent years on the use of the cooperative learning structure with computer-based instruction. They concluded that cooperation at the computer can produce some very positive results.

With the renewed interest in small-group learning in recent years, all forms of small-group work have come to be labeled as "cooperative learning". It is, therefore, not surprising that small-group work at the computers is also often erroneously referred to as cooperative learning. [Hooper 1992] cautioned that simply grouping students without shaping the environment may stimulate few cognitive or affective benefits. This is because positive learning outcomes from cooperative learning are contingent upon effective student interaction which is influenced by factors such as task structure, rewards, group dynamics, and interpersonal skills. As pointed out by [Cohen 1991], to optimize the benefits of cooperative learning, attention must be focused on the design of cooperative learning materials and activities.

The following is a brief description of a study that is being carried out to see how cooperative learning activities centered around the computer and the Internet can be organized to effect interaction and solve some of the teaching-learning problems in Malaysian secondary schools. This effort is a follow-up to earlier studies in Malaysia on cooperative learning. The earliest exploratory study indicates that cooperative learning is an effective teaching-learning approach that is congruent with the National Education Philosophy and the objectives of the Secondary School Integrated Curriculum [Gan 1992]. Subsequent studies on courseware development for cooperative learning have also produced very positive findings pertaining to achievement and the learning of higher-order thinking skills among students [Gan 1994][Gan 1995].

Objective of the Study

The main objective of the study is to use pre-planned structured cooperative learning activities which are centered around the computer and the Internet to effect interaction and solve some of the teaching-learning problems in the classrooms of Malaysian secondary schools. One of the problems in Malaysian classrooms is the large class size of forty or more students which makes it impossible for teachers to give sufficient personal attention to students, even those who are in dire need of it, such as the at-risk students. The other problem is the heavy teaching load of teachers which leaves them little time to source for interesting instructional materials or ideas to augment the standard prescribed text books.

Research Method

With regard to the two problems mentioned earlier, this study focuses on providing at-risk students - who need more individual attention from the teacher - the opportunity to work more closely with their teachers, and to play a leading role in learning activities in the classroom. This is achieved by training and appointing them to be the IT experts in small heterogeneous cooperative learning groups in the classrooms. These groups are given the task of sourcing for instructional and reading materials related to subject topics pre-determined by their teachers with the help of the researcher. The resources are obtained either from CD-ROM references or from the Internet. Thus, this is an activity that involves students in a more contributive role in the instructional process in the classroom, while at the same time presents a way of lessening teachers' work load in the sourcing of materials.

The at-risk students, who have been trained at the beginning of the school year in the use of CD-ROM references and the Internet, are in fact the group leaders who perform the following tasks: consult with their teachers on a regular basis what materials to source for, search and source for materials with the assistance of their groupmates who play the roles of language consultant, artist and editor; as well as train them in the use of CD-ROMs and the Internet. To effect such role specification in accordance with one of the principles of cooperative learning, each group consists of one at-risk student (the IT expert), one high-ability student proficient in English (language consultant), and two other students of average ability (artist and editor).

The IT expert sources for materials, gets the help of the language consultant in translating the materials from English to Bahasa Malaysia (the medium of instruction in Malaysian schools), and works with the artist and the editor to format and compile the materials. The materials can then be used by the teachers for incorporation into learning activities in the classroom. Over one school year, each of the ten groups of students (in a class of forty students) works on an average of one such project per month. Since the sourcing and compilation activities are done out of class, and IT facilities - which are confined to either the library or the computer lab - are limited and shared by the whole school, this frequency and arrangement have been found to be most ideal.

A Summary of the Research Procedure

1. Identification of at-risk students in two science classes (Grades 7, 9 or 11) in each of the two co-ed schools participating in the case study.
2. Collection of data pertaining to the profile of these at-risk students from records over the years.
3. Assigning all students in each class to heterogeneous groups.
4. Identification of topics and assigning of topics to groups.
5. IT training for the teachers.

6. IT training for at-risk students.
7. Collection of data pertaining to relevant achievement scores of all students in the previous school year.
8. Teacher observation, anecdotal reports while project is on-going.
9. Collection of data pertaining to relevant achievement scores of all students during the school year.
10. Comparison of students' pre- and post-project achievement scores and profile data, compilation of teachers' observations and anecdotal records.

IT Training for Teachers and Students

The training sessions for both the teachers and students include the following topics:

1) Introduction to the Internet
2) How to use e-mail, WWW, gopher, and telnet
3) Introduction to some educational sites
4) How to use search engines to search for information
5) Hands-on sessions on e-mail and WWW
6) How to retrieve and print information culled from the Internet
6) Introduction to various educational CD-ROM titles
7) How to retrieve and print information culled from the CD-ROMs

The Task Structure of IT-Based Cooperative Learning Activity

[Johnson & Johnson 1989] outlined five necessary components for effective cooperative learning: individual accountability, positive interdependence, promotive interaction, collaborative skills, and group processing. Based on his extensive review of classroom research on the achievement effects of cooperative learning, [Slavin 1990] concluded that cooperative learning methods can be an effective means of increasing student achievement, but only if they incorporate group goals and individual accountability. Learning activities in the classroom must therefore try to incorporate these components into their task structure to effect learning through productive interaction. IT-based group learning where students are simply placed in groups to work on an unstructured project at the computer, as is currently being practised in most classrooms, is unlikely to produce benefits.

A major premise in the design of this project is that it can produce the desirable learning outcomes when used as part of a carefully planned year-long instructional activity that is coordinated by a teacher. The following is an account of how the components of cooperative learning are incorporated into the task structure of the learning activity currently under study:

1) Individual accountability

To ensure individual accountability, all group members are required to master the materials they have sourced. One strategy suggested to the teachers is that a test on content be given to all students at the end of specified periods over the year. Individual reward is then given based on the average score of all group members. Based on the findings from their research on cooperative computer-based instruction, [Yeuh & Alessi 1988] suggested that this form of individual accountability be emphasized to create a feeling of fairness among all group members. [Rysavy & Sales 1991] also emphasized the importance of assigning each student a specific role in a cooperative learning group. To meet this requirement, each learning group incorporates four well-defined roles as mentioned earlier.

2) Positive interdependence

The strategy mentioned above of rewarding individual based on group's average score also ensures positive interdependence. This is supported by the IT-based activity which assigns a specific role to each student. Each student has to use his/her expertise to help his/her group come out with the product. Another strategy is giving group rewards based on group performance. [Yeuh & Alessi 1988] also suggested that group goal be provided in the form of a group reward so as to motivate everyone to work together. In this study, one of the group rewards is that if any group's presentation material is judged by the teacher and other classmates as good, it is put on the school's homepage and the researcher's homepage of educational resources for educators. In this way, the resource materials produced by the students' effort can be shared with the education community nationwide, and this makes them feel that their effort is being rewarded and recognized.

3) Primitive interaction

The series of tests, the assignment of different roles and tasks to different students in the group, and the reward system based on group average score, all encourage primitive interaction. The activity that involves translation work also provides weaker students (especially the at-risk students) the opportunity of getting help from the "language experts", and to better understand information culled from the various CD-ROM references and the Internet.

4 & 5) Collaborative skills and Group Processing

These are the skills that are pre-requisites to the successful use of cooperative learning activities. As such, teachers are encouraged and constantly reminded to allocate time for reinforcing collaborative skills and focusing on group processing whenever there is an opportunity.

Preliminary Findings

Due to unforeseen circumstances, the project started late and is behind schedule. As such, final results are not ready for analysis and only preliminary findings from teachers' anecdotal records are reported in this paper. For the final results, it is felt that it would be best to wait for a full school year of project implementation to collect students' profile data and students' achievement scores for comparison with those obtained from the previous school year.

In general, preliminary findings show that most of the at-risk students' attitude towards learning and school has improved. They show more interest in their school work, especially the project work; and are more willing to work on the class assignments. Their self-confidence has also improved as evidenced by their readiness to communicate with their teachers and classmates, and to participate in class discussion and presentation. The teachers' enthusiasm remain high as they become increasingly adept at and comfortable with allowing their students to play a more contributive and active role in the teaching-learning process in the classroom. They also feel that the students' presentations in class and the additional materials sourced by them have made teaching-learning activities in the classroom more interesting and stimulating.

Conclusion

Although no conclusive data are available just yet to prove the project's worth in improving students' achievement, the preliminary findings obtained thus far from teachers' anecdotal records are encouraging. At the very least, this kind of cooperative learning activities have, to some extent, provided teachers the opportunity to work with and pay more individual attention to the at-risk students who are in dire need of it. At the same time, the cooperative learning activities allow these students to play a more leading and contributive role in the classroom, thus improving their motivation and self-confidence. Last but not least, the teachers are no longer tied to their traditional role of one-way delivery of instruction without any input or participation from their students.

Abstract: Eighteen volunteer graduate students (nine males and nine females) primarily from the Department of Educational Psychology used a Windows-based statistical expert system (i.e., Statistical Adviser) to select the appropriate statistical technique for three research problems. Participants also completed a qualitative feedback survey, and an audit trail was used to analyze the decision-making strategy participants used in obtaining a solution. Participants' ability to effectively utilize the Statistical Adviser program to reach an acceptable solution appeared to be related to their ability to comprehend the research scenarios and translate aspects of the research scenario into concepts and terms that matched the program's queries. Female participants and participants with at least two previous statistics courses obtained more acceptable solutions. Also, participants who obtained a successful solution on the first research scenario were more likely to obtain further successful solutions.

Introduction

Though there have been significant advances in the field of statistics (e.g., structural equation modeling) over the past two decades, these developments have not always been incorporated into statistics and methods curriculum. Aiken, West, Sechrest, and Reno (1990) were alarmed by the findings of their survey of 186 of the 222 psychology departments in North America that the American Psychology Association identified as offering a Ph.D. degree. Only one-quarter of all recent graduates were judged competent at applying basic test theory concepts such as reliability, validity, and item analysis. One-third of all programs had no faculty trained to teach statistics and research methods, and topic coverage in most courses resembled that of 20 years ago. Increasingly, educators are exploring the use of computer-aided instruction (Varnhagen & Zumbo, 1990) and expert systems (Boncella, 1990; Saleem & Azad, 1992) in addressing these deficiencies.

Boncella (1990) suggests expert systems can play a vital role as consultants in the field of statistical education. An expert system can be defined as "the embodiment within a computer of a knowledge-based component, from an expert skill, in such a form that the system can offer intelligent advice or make an intelligent decision about a processing function" (Forsyth, 1984, p. 10). Expert systems attempt to tap into the domain knowledge and problem-solving strategies of experts, and make these accessible to novices.

Discussions of the issues regarding the development of expert systems in statistics were provided by Gale (1986) and Hand (1984, 1985, 1986, 1987, 1990). Hand (1985) has provided recommendations for expert systems in statistics. The statistical expert system needs to be adaptable to incorporate new knowledge and new techniques. It should explain why it is asking a particular question or recommending a particular technique. It should also explain technical terms so as to be user-friendly for the statistically naive. Ideally, the statistical expert system should recommend multiple techniques. Capabilities for both exploratory data analysis and formal hypothesis testing should be provided. The statistical expert system needs to adapt and make changes as the analysis occurs. For example, a different analysis may be required if the assumptions for a statistical technique are not met. The system must be flexible to enable users to backtrack when necessary and flexible enough to permit experienced users to override recommendations. Questions should be sensible and build on previous questions. An ordering of techniques is necessary. Users should be able to store their results. A teaching function would be helpful. Ideally, the program would be self-contained.

The Statistical Adviser (Sandals & Pyryt, 1992, 1993, 1994)is a Windows-based, graphical user interface, mouse-driven expert system that poses inquiries regarding aspects of the research problem, such as the number of variables, types of scales, purpose of analysis, fidelity to statistical assumptions, and then recommends appropriate techniques based on the decision-tree in *A Guide for Selecting Statistical Techniques for the Social Sciences* (Andrews, Klem, Davidson, O'Malley, & Rodgers, 1981). The program also includes a tutorial with a sample problem, a glossary of frequently-used statistical terms, and several appendices that provide reference lists, identify new or rarely-used techniques, and supply the syntax for executing statistical techniques in any of several computer statistical packages (i.e., SPSS, SAS, SYSTAT, MYSTAT, and MINITAB) on various computer platforms (i.e., WINDOWS, DOS, MACINTOSH, and UNIX). The purpose of this study was to conduct a field validation of the "Statistical Adviser". The intent of the study was to determine if the statistical decisions participants obtained using the Statistical Adviser expert system were congruent with decisions recommended by academic statisticians. The researchers were also interested in the decision-path participants used in coming to a statistical solution, and in any differences related to age, gender, degree program, and number of statistical courses taken.

Method

Participants

Eighteen volunteer graduate students participated in a field study in the spring of 1995. Gender representation was balanced with nine male and nine female students, and all students except one were from the Department of Educational Psychology. Twelve of the eighteen participants were completing a Master's degree and six were completing a Doctoral degree. Participants had taken an average of three statistics courses (mean = 3; S.D. = 1). Participants' ages ranged from 22 to 46 years, with a mean of 32 years and standard deviation of 6 years.

Measures

Eight research scenarios previously used by Sandals and Pyryt (1994) drawn from Pagano (1994) served as stimuli. The scenarios represented two chi-square problems, three correlation problems, and three analysis of variance problems. Each research scenario consisted of a brief paragraph describing a sample research problem and an accompanying table. Participants used the bottom of each scenario to record the statistical technique recommended by the Statistical Adviser program.

For the purpose of this field study, the Statistical Adviser program was modified to create a "dribble file" of each computer screen. This file served as an audit trail of each participants' decision-path as they developed a solution for the scenarios.

A Statistical Adviser Feedback Survey form solicited participants' feedback to four open-ended questions, namely: Please describe your impressions of the research problem. Please describe your impressions of the Statistical Adviser. In what ways could the Statistical Adviser be improved ? Can you identify specific situations where you would find the Statistical Adviser a useful tool ? Participants were also asked to identify their age, gender, current degree program, faculty, and total number of Statistics courses taken.

Procedures

Participants were recruited using descriptive information sheets posted across the university campus and verbal solicitations in several statistics classes. Students who expressed an interest were given an information letter and consent form. After granting verbal and written consent, participants were provided with three research scenarios representing a chi-square, correlation and analysis of variance problem. For each type of problem, the particular scenario was randomly selected and the chi-square, correlation and ANOVA problems were presented in random order. Participants were asked to use the Statistical Adviser program to determine an appropriate statistical technique for each scenario. An "audit trail" of the decision-path followed by each participant was automatically logged by the program in a "dribble file". When participants were satisfied with the recommendation presented by the Statistical Adviser, they recorded their answer on the research scenario sheet. Upon completion of the three scenarios, participants responded to the Feedback Survey form.

Results

Research Scenario Solutions

Participants' Statistical Adviser-assisted statistical decisions were compared with the decisions recommended by academic statisticians (i.e., chi-square, correlation, analysis of variance). An initial analysis of the data revealed that only four participants (22%) obtained the chi-square solution, one participant (6%) obtained the correlation solution, and one participant (6%) obtained the analysis of variance solution.

An inspection of the decision-path audit file revealed that several participants had distinguished between dependent and independent variables in the scenarios. This prompted the Statistical Adviser program to recommend the statistical techniques of Goodman and Kruskal's tau b, regression, and F-test for the chi-square, correlation and ANOVA scenarios, respectively. An examination of the research scenarios suggested such an interpretation might be justified. These alternative responses were therefore accepted, resulting in eight acceptable responses (44%) for the chi-square / Goodman and Kruskal's tau b scenario, eight acceptable responses (44%) for the correlation / regression scenario, and two acceptable responses (11%) for the ANOVA / F-test scenario. Six participants (33%) obtained two acceptable scenario solutions and one participant (6%) obtained three acceptable scenario solutions. In total, participants obtained acceptable solutions for 18 of the 54 (33%) scenarios.

The low number of acceptable responses for the ANOVA scenario suggests that participants had more difficulty comprehending this scenario. The ANOVA scenario required participants to navigate slightly more steps (8) in the Statistical Adviser program logic than the correlation (4), regression (7), chi-square (6) or tau b (7) solutions, and required participants to respond to more complex inquiries (e.g., assumption of homoscedasticity across levels of the independent variable). Participants effectiveness in reaching an acceptable solution may have been influenced by their comprehension of the research scenarios and the complexity of the decision-path required to obtain an acceptable solution.

The scenarios were presented in random order, and participants obtained acceptable solutions for seven of the first scenarios, five of the second scenarios, and six of the third scenarios. Of the seven participants who obtained an acceptable solution for the first scenario, three (43%) obtained an acceptable solution on the second scenario and four (57%) obtained an acceptable solution on the third scenario. Six of eight participants (75%) who obtained an acceptable chi-square / tau b solution also obtained an acceptable correlation / regression solution. Participants' effectiveness in reaching an acceptable solution may have been influenced by their ability to extract statistical concepts from the research scenario and translate those into responses to the program's queries. Those who were able to accomplish this with the first scenario (or with the chi-square or correlation scenario) were more likely to obtain acceptable responses with other scenarios.

Audit Trail

An examination of the audit file revealed that 32 of 36 wrong answers (89%) were related to two basic errors in participants' interpretation of the scenarios: number of variables, and type of scale (i.e., nominal, ordinal, or interval). In 18 of 36 instance (50%) where participants obtained an incorrect solution, they had misinterpreted the number of variables involved in the problem (see Figure 2). For example, in ten of these instances, participants interpreted the multiple groups in the ANOVA scenarios as multiple variables rather as multiple conditions of a single variable. Several participants also interpreted the two dichotomous conditions in the chi-square scenarios as four variables rather than as two two-point variables. In 14 of 36 instances (39%) where participants reached an incorrect solution, they had incorrectly identified the type of scale (i.e., nominal, ordinal, or interval). For example, six participants identified an interval measure in the correlation scenario as nominal or ordinal. In the ANOVA scenarios, several participants interpreted the ANOVA conditions (e.g., age groups) as an ordinal rather than nominal measure.

Demographic Variables

The number of acceptable responses were cross-tabulated with participants' age, gender, degree program, and number of Statistics courses taken. An examination of the table suggests that female participants and those who had taken more than two statistics courses obtained more acceptable solutions. Since both male and female participants had taken an average of three statistics courses (i.e., mean = 3, S.D. = 1), these factors appeared to be independent of each other. Participants' age and degree program appeared unrelated to their scenario solutions.

Qualitative Feedback

All participants described the research scenarios as simple, straightforward and understandable, using terms such as: "clearly written", "straightforward", "elementary", "basic" and "realistic". Twelve participants (67%) viewed the program positively, with one expressing reservations about the target audience (i.e., experts vs. novices). Participants with positive views believed the program was "well-laid out" and "easy-to-use", and appreciated the glossary, appendix and tutorial features. Five participants (28%) suggested the program would be useful in working through problems in a statistics course and four participants (22%) believed the program would be helpful in their thesis or dissertation work and in other research projects. Several participants also noted the program's potential for exploring various approaches to problem analysis and clarifying a research design. Four participants (22%) expressed strong negative opinions of the Statistical Adviser program (e.g., "confusing and intimidating") and three other participants (17%) expressed some concerns that the program "required a high level of background knowledge" and might be "designed for expert use".

Ten participants (56%) suggested the program could be improved by providing examples of key concepts and terms, such as examples of various types of scales. Five participants (28%) also recommended that simpler terms be used throughout the program. Other suggestions included the incorporation of a hypertext or "find" function in the glossary, addition of a global "help" function, an expanded introduction, and more graphical rather than textual display of information.

Discussion

Participants ability to effectively utilize the Statistical Adviser program to reach an acceptable solution appeared to be related to their ability to comprehend the research scenarios and translate aspects of the research scenario into concepts and terms that matched the program's queries. Female participants and participants with at least two previous statistics courses obtained more acceptable solutions. Also, participants who obtained a successful solution on the first research scenario were more likely to obtain further successful solutions. Two-thirds of the participants expressed positive views regarding the Statistical Adviser program, and one-quarter believed the program would be a useful tool in working through problems in a statistical course and/or conducting thesis, dissertation and other research. Several participants also appreciated the program's potential to explore various approaches to problem analysis. Jackson, Edwards and Berger (1993) note that the essence of an effective computer-based design is the program's ability to "facilitate and regulate the exploration of alternatives on the part of the learner" (p. 415). Expert systems that stimulate thinking and prompt learning may be more effective than those that only provide expert advice and recommendations.

All participants described the research scenarios as simple and straightforward. However, participants reached acceptable solutions for only one-third of the scenarios. In almost 90% of the instances when an unacceptable solution was obtained, participants incorrectly identified the number of variables or type of scales involved in the scenario. In their written comments, more than half the participants suggested that the program should review and provide examples of key concepts and terms such as types of scales. Despite the fact that participants had taken an average of three statistical courses, they appeared to struggle with some basic statistical concepts. Mazur (1992) argues that a weak link in many interactive computer tools is inadequate supportive text that: orients users to the program's capabilities functions, provides content clarification when required, and motivates and encourages exploration. Though the Statistical Adviser incorporates a tutorial, glossary and several appendices, participants expressed a desire for further support in understanding key concepts and terms through the incorporation of extended help functions and a glossary search feature.

Several participants also expressed concerns that the program required a level of background knowledge they felt was beyond them or that the program was designed for use by experts. These comments, and the relatively low number of acceptable solutions, may reflect the difficulty some participants had in translating the research scenarios into the concepts and terms that the program's queries required . Jonassen, Wilson, Wang and Grabinger (1993) argue that many expert systems utilize objectivist designs that insulate users from the reasoning of the underlying knowledge base and disengage them from the decision-making process. Users who are unable to replicate the system's model in their own thinking may experience the expert system as confusing and frustrating. Such comments highlight the fact that although the IF-THEN rules and reasoning of the expert system reflect the wealth of the expert's knowledge, they can also impose a prescriptive sequence of interactions that prove counter-productive with some users. Jonassen et al. (1993) challenge expert system developers to explore constructivistic designs that enable users to represent their own thinking or represent causal logic in a content domain. Schwier (1993) echoes this concern and suggests that computer-based multimedia tools move from a prescriptive approach to a democratic interactive environment where users play a greater role in the interactive process. Yaziçi, Muthuswamy and Vila (1994) also stress the importance of flexible interface designs that accommodate varying cognitive styles and skills, particularly in high complex tasks and interactive decision-making processes.

Sandals and Pyryt (1994) found that first time users of the program had difficulties in the initial field-test. Results from the present field-test suggest that the addition of a single tutorial demonstration does not enhance a novice user's ability to navigate the Statistical Adviser to make correct statistical decisions. These difficulties can be minimized through demonstration and guided practice in research methods and statistics courses, which is currently being done at the University of Calgary.

The use of the audit trail in the present study yields interesting information about a respondent's interaction with the computer. This feature will be retained in future versions of the program.

In addition to additional field tests of enhanced versions of the Statistical Adviser, future research with this tool should focus on its use in research methods courses. With the glossary, reference section, and computer package information, the Statistical Adviser can easily be used as a statistical reference work.

3D Interfaces for Training :
"Knowledge Cities and Learners as Tourists"

Alessandro Giordano
Consorzio Multimedia, Catania, Italy

Daniela Giordano

giord@alcor.concordia.ca

Abstract: The paper illustrates how three-dimensional interfaces afford building learning environments that support a guided exploratory approach to learning, and how such support can be derived from the metaphor of the city as seen by a tourist. We investigate possible representational mappings between the urban landscape and the attractions of the city. The three-dimensional city-based symbolic representation works synergetically with the overlaps that exist between the learning process and the exploration of an unknown place, starting from the organization of the trip. Learners develop their competencies gradually and according to their preferred approach, by traversing the city landscape and by engaging in simulations of the tasks. The approach is illustrated with 3D Studio City, whose urban landscape has been conceived to learn a three-dimensional modeling and visualization software.

1. Introduction

Simulation as instructional strategy if often advocated to support constructivistic approaches to learning and as being intrinsically motivating. It naturally fits instructional situations in which there is a causal model, either quantitative or qualitative, underlying the phenomenon or process to be understood or the task to be learnt.

Approaches to the design of instructional simulations vary from the use of simulation in a rather didactic fashion, with emphasis on its illustrative power [Reigeluth & Schwartz, 1990], to the use of simulation for more open-ended exploration [Duchastel, 1993], to the use of simulation for recreating situational scenarios in which the learners actively participate, as in the goal based scenario (GBS) framework [Schank et al., 1994].

Some strengths of simulations. i.e. affording the possibility of learning by doing and learning from mistakes by experiencing the consequences of performing an action, are especially relevant in domains characterized by highly technical and conceptually demanding tasks, as for example electronic circuit design or troubleshooting [Lajoie & Lesgold, 1989]. Structured practice in a simulated environment can be complemented by an exploratory or discovery component added to the learning environment, to jointly develop a sense of "what" is possible and of "how" it is possible. Examples would be learning a programming language or learning to use advanced features of software applications (e.g., a CAD environment, a word processor). In such situations learning procedural elements is intertwined with the need of developing a generative mental model of the tasks and of the domain that facilitates future learning.

A software tool is by itself a microworld, in which the consequence of actions can be immediately seen. However, initial barriers due to the complexity of procedures or to the fact that the underlying model of the system is not self-evident, most of the times discourage a learning by directly practicing in the environment. Classic solutions to this problem are the set of guided exercises that are commonly found in manuals. Yet such approach is poor with respect to contextual feedback on results and flexibility of exploration.

This paper shows how the metaphor of organizing and doing a trip to a city whose urban structure mirrors the structures of the task and contents can be a suitable framework to design learning environments for technical contents. The three dimensional landscape of the city affords layering the learning difficulties without compromising a unitary view of the nature and soul of the city. The approach is illustrated by means of a learning environment prototype that makes possible a trip to 3D Studio City, whose urban landscape is designed to learn a three-dimensional modeling and visualization software.

2. Metaphors or Simulation?

The approach that we propose is hybrid, because of the introduction of two main metaphorical components, the trip and the city landscape. The two metaphors operate in synergy to mediate the access to "spaces" in which an adequate degree of context and task fidelity [Alessi, 1988] is ensured. The reasons why there is no serious clash with the requirement of situational fidelity of "pure" simulations, are illustrated in the following.

2.1 The Trip Metaphor

The metaphor of the tour has been often used to introduce the organization of the contents, to provide a navigational structure, or to provide additional perspectives on the contents mediates by "guides". We extend this use based on the consideration that some aspects germane to the trip experience map easily to aspects fundamental to learning. In this sense we can consider the trip as an "experience" metaphor.

A trip to the same place can be organized in very different ways, based on constraints such as purpose, time and money available, interests and preferences of the traveler. This sort of dimensions are usually discussed in a travel agency, in the phase of trip organization. In the successful organization of the trip two factors concur: an accurate "self-analysis" on time, purposes, and autonomy degree, and an "agency" that is able to offer a customized solution. Travelers can be adventurous explorers who just want a ticket to their destination and organize everything else on their own, while others are at ease when everything is planned and organized in advance, and need local guides and support. This is practically isomorphic to how learners tend to approach a task based on their dispositions. In the same fashion, there is a varied typology of trips that maps nicely on the overall purposes for which a learning enterprise might be undertaken. Examples of trips are: a "relaxed" vacation, with plenty of time available to "dilute" experiences; a "standard" stay of one week, which implies a careful selection of what to visit and possibly some time available for unplanned explorations.

One can choose a destination because of some known attractions (e.g., the Tour Eiffel in Paris) which trigger the initial interest. However, most is learnt about the city when one is on site. In the most successful cases, the progressive acquisition of information leads to uncover interesting sides of the city that one would have not thought of. This is made possible by an effective deployment of information available at the right time with increasing detail. One can drop by at the tourist office, talk to the receptionist at the hotel, meet interesting people, or just follow the indications of a knowledgeable and responsive guide.

Another relevant aspect of the trip experience concerns the common practice (and wisdom) to monitor if the budget is respected, how much time is available for detours and unplanned excursions, how much of the attractions offered by the city has been enjoyed. In a learning situation these element may provide an anchor for relevant metacognitive processes. Also, the trip metaphor affords the opportunity of introducing some game component to make the environment more motivating [Malone, 1981]. Interestingly, the limits of application of the trip metaphor are not intrinsic, rather they are to be found in the natural or plausible correspondence that can be established between the trip destination and what has to be learnt.

2.2 The City Metaphor

Our cities are not conventional ones. Their architecture, their urban layout, their resources concur to create a conceptual landscape which maps the task and domain to be learnt. The approach is similar to the technique of scientific visualization, i.e., the visual representation of abstract data to detect patterns and meaning.

The effort required for building a three-dimensional representation to map the contents in the form of a urban landscape is justified especially when the domain is too abstract, broad and superficially homogeneous, and its basic structure and organization are not self-evident. The main challenge in finding effective three-dimensional representations to organize contents, domains, or practice scenarios aims to provide relevant flexible (varying in level of detail or perspective) but unitary views.

The urban landscape can be designed by first mapping specific topics to peculiar attractions of the city (typically buildings and sites) and then by mapping the other urban elements or facilities offered by the city into resources likely to be used in any learning situation. By associating a building to a specific topic, information on the type of content, on its context, and on the kind of activities to be performed, can be conveyed at a glance, based on: the *functional destination* of the building (e.g., is it a museum, a factory, a commercial center, a historical monument, a recreational center, and so on); the *style* or *shape* of the building (to be used if there is not an immediate mapping with the functional destination); the *volume* of the building, that might be related to the amount of information or to the degree of difficulty; the *location* of the building (e.g., downtown, the historical nucleus, the modern area, the residential area). The *height* of the building is a convenient way to

421

denote increasing difficulty and more accomplished levels of expertise. In this case buildings are organized in floors and elevators are used to move from a level of difficulty to the other. Typically, downward exploration is always possible, whereas moving upward requires a pass, that can be related to entry requirements, or can be earned as more aspects are mastered.

The kind of topic also has an impact on the design and organization of the interior of the building. The organization of the interiors offers many opportunities for inducing mental models of the task or favoring certain patterns of exploration. For example, rooms can be laid out according to circular patterns for independent access to each room, or according to corridors that suggest a visiting path. Most of the "learning by doing" component takes place inside the buildings, where every room or space can be thought of as a scenario in which specific activities can be performed and their consequences are simulated.

Other elements amenable to creative utilization in the "knowledge cities" are: 1) the *hotel* (to rest, to reflect, to plan future excursions); 2) the *theater*, the *movie*, the *convention center* (where, for examples, some special events are scheduled, such as demonstration shows or round- tables with leading experts that are visiting the city); 3) the *gym* (for some special practice workout) and 4) the *pub* or the *café*, where opportunities for socialization and exchanging opinions are found.

Navigation in the knowledge cities is made possible by the transportation system and by free movements inside the buildings. A surface transportation system (as opposed to an underground metro) can indirectly be used to provide an overall view of the city, even of those area that currently are not part of the exploration plan of the learner, and the stops can be designed to maximize efficiency in visiting certain sites. The city metaphor carries with it well known and tested navigational patterns that are part of everyone experience. The third dimension is a most important component to attain a sufficient degree of fidelity to effortlessly activate such behavioral patterns, and to reveal aspects normally lost or hidden in conventional organizations and representations of contents. Such considerations clarify the claim that one of the advantages of introducing the "city overlay" over simple collections of simulated scenarios for action and practice is that the city naturally provides a representation for the boundaries of the domain and that its resources are inherently organized for access and fruition.

3. A Case Study: "3D-Studio City"

We illustrate the synergy between the trip metaphor and the city metaphor with "3D-Studio City", a training environment for a software for modeling, visualization and animation: Autodesk 3D Studio. This prototype demonstrates some pedagogical issues and design solution adopted for building a viable interface to a three-dimensional world. The prototype architecture consists of three main components: 1) the city three-dimensional model (layout of the urban elements and of the transportation system); 2) the detailed model of each site, including the interior, the information and resources uniquely associated to the site; those directly accessible from the site; and the scenarios for practice and action; 3) the engine governing access to sites and the dynamic update of the visit opportunities. In the following how the prototype works is described.

3.1 Arranging the trip

The program starts by placing the learner in a *travel agency* [Fig.1], where different types of tour can be arranged. One can interact with the *agent* who introduces the resources of the City and possible ways to organize the stay. The purpose of the trip can be: for vacation, for culture, for business. Such typologies correspond to the level of expertise that the learner would like to attain (introductory, intermediate or advanced), and are used by the program to customize the suggested itineraries, the way certain type of information will be presented and how to test the learner. One can browse the tour description available on the table, and before committing to any decision can opt for the "Fun Tour", the shortest trip with emphasis on the more appealing attractions of the city. Agents also explain how time flows in the City and the role of the Credits. Time is measured in days that pass whenever the traveler will return to the hotel for the night (i.e., stopping the training session to resume it the next time). Credits are a way to make the learner aware of the effectiveness of their navigation choices. They are spent whenever a threshold of allowed number of visit to a site is exceeded, or when detours from the planned excursion do not lead to any accomplished result. Granted all the above options, the visitor can decide for the joys and pains of a self-organized trip, or resort to the services of personal *Cicerbots*. Finally, city maps, suggested itineraries, transportation tickets, passes for accessing the sites of interest at the right difficulty level are handed over to start the journey.

3.2 Visiting 3D Studio City

After enjoying an air view of 3D Studio City from a plane, the traveler lands at the *airport*, where a *passport control* is required only if the traveler has not chosen a personalized tour at the agency. This allows for the program to collect personal information about the learner to manage training sessions spread in time. The first step is to take the *Shuttle* either to go to the Hotel or to reach a site selected from the map. For visitors who do not know anything about the city, at the Hotel there is a *Currency Office*, where, before starting their journey, visitors can get acquainted with the minimal definitions and concepts that allow a proficient visit of the city. Candidates for a first stop are the *"Applications Museum"* and the *"Techniques Museum"*. In the city metaphor it is fundamental to keep the typology of the building as close as possible to its real meaning. In a museum, for example, deeply diverse artifacts are collected together under a common denominator, often mirrored in the floors organization. Floors of the Application Museum correspond to: architectural applications, industrial design, multimedia programs, electronic art, all artifacts being produced with Autodesk 3D Studio. The Techniques Museum is organized in four floors, corresponding to Theory of color, Shooting techniques, Fundamentals of animation, and Graphic formats.

The core of 3D City are its 6 *"Modular Palaces"*: 2D-Shaper, 3D-Lofter, 3D-Editor, Material-Editor, Keyframer, and Kinematic. How to reach a Modular Palace by taking the Shuttle and is shown in [Fig. 2].

While in the Shuttle one has a situational view of the area that is being traversed (big window on the right) and information on the more general context (small window on the left). One can ask for stops for training, or for recreational stops. A 'search for" option is available to locate specific rooms or objects within a building.
Each building has three floors, which correspond to a low, medium and high difficulty level. In every floor are rooms with scenarios for activities. [Fig. 3] illustrates one of such situations.

Figure 3: Selecting a scenario for activity in the Creation Room of 3D-Lofter Palace

The learner is currently in the 3D-Lofter Palace, and each room in the floor (shown in the Palace map) has a number of objects that might be created by applying specific sequences of commands. The purpose of the simulation is to experiment the effect of the application of certain commands sequences. Once the practice scenario has been chosen the learner is presented with an interface [Fig. 4] in which a selected portion of the real 3D Studio software with the relevant commands is available to experiment. Actions lead to result that are immediately compared with the intended one, and a visual record of the effects achieved is available too.

The learner can take a break by dropping by at the *Internet Café*. This is the place where most of the social life of 3D City takes place. One can join the lively world of Internet based discussion groups around the topics of major interest, and participate actively, by posing questions and seeking answers. The City affords many more attractions. In the surroundings there is the amazing *Silicon Park*, where one can get acquainted with the possibilities afforded by the IPAS (Image, Procedural, Animated, Solid external processes) module "Silicon Garden" to create lawns, trees, gardens, golf courses, forests, and so on. The *3D Special Effects Amusement Park*, has the *Planetarium*, for IPAS effects such as stars, comets, planets, and, why not, even fireworks; the

BEST COPY AVAILABLE

Aquarium, for IPAS related to waves, sea surfaces, vortexes, liquefaction effects; and the *Biodome* where all the secrets behind rain, snow, wind, fire, smoke, vapor can be revealed. For the more advanced learners, a visit to the *Production Studios*, will satisfy curiosity on video post production. Concerning practice, 3D Studio City supports a twofold approach: practice is always embedded in the simulations driven by the learner; and there is the *fitness center* to be visited for special workouts "out of context", where the learner is challenged to solve exercises to ensure that "memories" of the trip are vivid and clear. A training session can be concluded by returning to the hotel, with the warning that too many interruptions (stay overnight) could not be productive. Opportunities offered by the city are dynamically updated according to the learner progress. This is reflected in the hotel a bulletin board displaying the upcoming special events, so that if they meet current goals and interests, a variation to the trip for the day after can be wisely planned. The original purpose of the trip can be re-negotiated by contacting the tourist office, provided that the learner is aware of the resources that will be needed to do so (i.e., more time, more effort, and so on). In the meantime, as long as the tourist visits 3D Studio City and participates in its culture a very sought after certificate is slowly composed, like a puzzle: the honorary citizenship of 3D Studio City, for distinguished cultural or technical contributions.

4. Some Design Issues

The city metaphor is quite flexible and can be extended or adapted for other situations. We have shown how it might work in a technical domain. The mapping task is facilitated if the purpose of the learning environment is to deal with knowledge that is intrinsically associated with a city, e.g., geography, history, economics, culture and traditions, or aspects of science and technique. However, to be successful, the design of "Knowledge Cities" requires careful consideration of some issues. First, designing the landscape of the city is not a straightforward task. For the result to be plausible and enjoyable it is necessary the integration of notions of urban design and the mastery of 3D modeling tools in an approach to landscape design that is fundamentally guided by interactivity principles [Giordano & Giordano, 1995]. Effective layering of information seems to be more an art than a science. Issues to take into account concern whether partial disclosure of what is in the upper floors is needed to motivate the learner to earn the pass or whether curiosity alone is sufficient. Future formulation of design principles looking at the trade-offs of hiding and disclosing information with respect to the creation of a robust and accurate mental model in the learner would certainly be useful. Ensuring the live link to the discussion group on the technical matters, whenever these are available, seems to be a fundamental component of the knowledge cities. A main consequence is a simplified design of the agents populating the city, who are mainly confined to the role of providing introductory information and eventually pointing out more relevant resources in the Internet Café. An open issue is finding three-dimensional representations for contents and information both flexible in detail level and still unitary. We are currently experimenting with symbolic three-dimensional representations of recurrent types in learning situations, e.g., fundamental topics, simple but time consuming tasks, operations that are not time consuming but are conceptually sophisticated (expert tricks), notions of difficulty, relevance and interest. Also of concern is the feasibility of adapting some aspects of the landscape, the maps, and the navigational tools to the preference of the user, based on a personal semantic of shapes provided by the user by answering few questions on the meaning that certain shapes convey.

Abstract

This paper integrates the theoretical intersection among ethnography, feminist theory, and epistemology within the larger context of an interactive learning environment for distributed electronic research communities. The particular environment examined is a Web-linked book, currently in press with Lawrence Erlbaum Associates, *Points of Viewing Children's Thinking: A Digital Ethnographer's Journey* which will be one of the first books affording readers an ability to annotate and view video segments described in the text. A generic tool, Web Constellations, for this interactive book/on-line-data link is described that enables researchers to add their views and interpretations and then to use this tool for their own knowledge building collaborative research data sets. Our intention is to provoke the research community into rethinking its traditional assumptions about solitary scholarship, explaining how digital media can be used to create more collaborative research environments.

Introduction: Expanding the WWW as a Platform for Shared Research

The World Wide Web offers a vast range of possibilities in the building and sharing of knowledge — possibilities that have yet to be fully understood by the research community across the social sciences. Although the web is full of activity, specific tools have yet to be devised that focus on a critical aspect of conducting research on the Web, the fact that data, text or video, can more readily be changed, moved, shared, and reconstituted. Within the purview of this paper, we hope to address several issues posed by the promise and crisis in this form of participatory knowledge construction. A new research tool, called Web Constellations, has been designed to encourage multiple users to work collaboratively on shared data sets. While the theoretical basis of Web Constellations has been to look at the more narrowly focused aspect of how traditional notions of cultural contexts might change in and through our roles as researchers using the Web, our technical goal has been to build this prototype in a way that enhances our abilities to tell our research "stories" on the Internet and to encourage others to share their stories.

Theoretical Framework: Creating Participatory Research Communities

A window of opportunity has finally opened upon levels of collaboration that once only "radical" feminists identified as the missing link in the history of knowledge construction (Grumet, 1988; Harraway, 1991; Turkle, 1995; & Britzman, 1993). Tools for collaboration using networked technologies offer researchers the opportunity to connect and negotiate interpretations leading to theories of knowledge that are more inclusive.

The Web offers the opportunity for this more inclusive cross-cultural paradigm concerning the generation of human knowledge — a paradigm that also runs parallel to the tenets also embedded within situated learning (Lave, 1988; etc.), ethnographic research methodology (Geertz, 1988; Lather, 1996), and constructionist knowledge-building (Papert, 1980& 1996; diSessa, 1985; Bereiter and Scardamalia, 1985).

The Web also offers the basis of building collaborative learning environments. One of the authors of this paper has also been using the Web to build a collaborative work-site, known as Studio A, that supports high school programs in Information Technology Management (Willinsky & Forssman, 1997). The students form project teams through the Web site to support the information technology requirements of their school and community, including training, curriculum support, repair, management, and planning. One area where this collaborative problem -solving service-driven approach has proven effective is in addressing the masculine space associated with technology, with more young women being drawn to using technology to provide services and find greater independence in the curriculum (Willinsky, 1996).

Our history shows, for example, that women have traditionally been excluded from the use and design of technologies. Research environments, whether in a physical location on a tract of land or in a networked environment, need to be places where ideas can grow and be nurtured with one's peers and "teachers" regardless of gender, class or race. They need to be places with private and public boundaries, where views can be challenged, and where ownership of ideas, especially when these ideas are socially constructed, is respected and acknowledged within the community of practice. Researchers using this electronic platform for intellectual discourse need to not only be voyagers or navigators using the tools for "gathering" data; they need to see this space as their social responsibility, a space to initiate discussion, to draw attention to its potentials and pitfalls, and to test the enactment of these technologies. This platform, or what one of us has termed a "platform for multi-loguing" (Goldman-Segall, 1995), ensures that researchers will be making informed decisions about the technologies on which scholarly work is increasingly dependent.

Data have recently become available to readers in seemingly less mediated forms through the use of Web-based technologies. Some would say that these raw and less filtered data are more accessible and thus more "truthful" than the highly constructed final versions of texts that appear in our current media — books, journal articles, films, and video reports. However, the film ethnography community has taught us that even the raw data (or footage) not yet molded into products are shaped by the author's choice, framing, or handling, and, that "the value of an ethnography or a film ... must be judged on the appropriateness of what has been included and how it has been handled" (Heider, 1976, 17). Framing and handling data are mediated actions that add filters. And although putting data on the Web for multiple readers to view is perhaps less mediated than the publication of only the analyses, researchers are still framing their data with constructs that reflect their own reference points, selecting which data are most representative for what they want to demonstrate (Minh-Ha, 1992). In short, framing is the optimal word here. How we frame our data consists of more than the categories within which we place them for the analyses. Analyses are taking place at every juncture as we place our views, our points of viewing, upon what we choose to select as "data" and how we juxtapose these data with other data.

Networked technologies can change basic search and retrieval methods by enabling the context of the story to accompany the less descriptive data markers or key words — the qualitative to accompany the quantitative — without forfeiting the robustness of the categorical. To start this form of multi-voiced interactive storytelling, one needs to start with annotation tools, simple spaces to comment upon what was seen, heard and read by readers and authors alike and build clusters of segments, scenes and scenarios, and finally stories that convey our interpretations of events.

Designing a Web-Linked Book for Shared Knowledge Construction

This project goes about exploring the possibilities of knowledge building on the Web in two ways, both historically, in a way that moves into the future, and practically in building an exemplar and templates. The historical approach places these new technologies in relation to previous print technologies for organizing learning (Willinsky, 1991; Willinsky, 1994); it also examines the political economy of the Web that affords a new means of educational empire by new media for the dominant cultures of the globe (Willinsky, in press). But in support of this historical analysis, we also seek to shape the future of the Web by demonstrating a deliberately collaborative knowledge building environment, featuring a bridge between historical and future technologies. We also wanted to present our data in ways which afford many points of viewing. And, to establish a way that researchers could learn from on-line data, while recognizing their tendency in this slippery medium to be manipulated (Goldman-Segall, 1995). Addressing these issues, we established an exemplar that yields alternative conceptual frameworks.

The Template

The first template we are developing is a Web-linked book, currently in press with Lawrence Erlbaum Associates, *Points of Viewing Children's Thinking: A Digital Ethnographer's Journey* by one of the authors of this article, Goldman-Segall. It is probably be one of the first books affording readers an ability to annotate and view video segments described in the text. Building upon her decade of experience in designing video data analysis research tools, such as *Constellations*, a template for this interactive book/on-line-data link has been designed for researchers to add their views and interpretations using a customized version of Web Constellations. The project builds upon and extends an existing software tool, Constellations designed by Goldman-Segall and Halff, bringing it into a Web-based environment. This prototype aims at stretching the Web's ability to facilitate collaborative, Web-based knowledge construction as well as a critical assessment of the potential impact these technologies can have on the social sciences.

Overview of Methodological Considerations

To encourage conversations with those participating in this new medium, whether they be other researchers or members of the global community at large, we became conscious of our responsibility to be as inclusive as possible in our role as researchers while we researched the research process in and through this new medium. After all, greater inclusivity and access is part of the promise of this new technology.

We started with a premise gleaned from our previous works that paradigms are changing and we now have tools for a more expressive form of inquiry. For example, ethnographies can use a variety of media forms to convey and create meaning in the minds of readers and viewers (Eisner, 1992). In fact, one of our researchers' previous research indicates that research on the Web is already a collaborative platform where those we study can become part of our research process and those who read the results of our studies can enter into a conversation with us and with those studied (Goldman-Segall, 1993, 1995 & in press).

The historical inquiry that we are undertaking attempts to move our thinking (1) backwards through a history of literacies that considers the knowledge building capacities of the text, illustration, table, book, library, encyclopedia, and database, to put developments on the Web into proper perspective, and (2) forward through speculative forms of computer science (Moravec, 1992), cyborg manifestations and manifestoes (Haraway, 1991),) and science fiction depictions of cyberpunk in the novels of William Gibson and others. This work has been designed to inform and form part of the content of the Web development that this project represents.

The obvious first step in this construction process was to think through what new technologies and global networks offer in ways of collaborating on the ethnographic research process by consulting with both researchers and research subjects, and by exploring theoretical and speculative envisionings of the technologies' potential. The works by and conversations with Glorianna Davenport at MIT (1996), Ron Baecker at University of Toronto (Harrison & Baecker, 1991), and Lucy Suchman at Xerox Parc (Suchman, 1987), David Jonesson at University of Pennsylvania (Dufffy & Jonesson, 1992), and Kellogg Booth at UBC have been instrumental in our design. In the second step, we have drawn up existing software tools that facilitate the building of on-line data analysis tools. Our third step has been to design an environment for the use of Web Constellations, using *Points of Viewing Children's Thinking: A Digital Ethnographer's Journey*. And in our coming research, we will address the quality of interaction, collaboration, community building, and finally the understanding of knowledge that arises in working with research data and analysis in these new ways.

Bringing A Book to Life: A Web Site and a Tool Called Web Constellations

The design of the book's web site integrates the principle themes of the book- storyreading, storymaking, and storytelling — with the research methods described and data presented. Readers can view source video as part of their reading of the book; make their own story by annotating video pieces and building meaningful constellations of video pieces; and tell their story by making their annotations and constellations avaliable to other readers, entering into a conversation with a distributed community. Web Constellations enables users to view a chunk of video, for example, and add annotations, and cluster the (star) chunks into constellations. In this way, the coded database of material becomes an expanding body of material for collaborative research.

A tool in its own right, Web Constellations enables researchers to create stars [Fig. 1] from any piece of information which can be described by a URL, such as a chunk of video on a web server, tag those stars with keywords, add annotations to their stars and other resarcher's stars. This coded database of material becomes an expanding body of material for collaborative research as users locate stars based using a simple search mechanism [Fig. 2], cluster stars found through searchers into constellations, and continue to annotate stars and the constellations built from them.

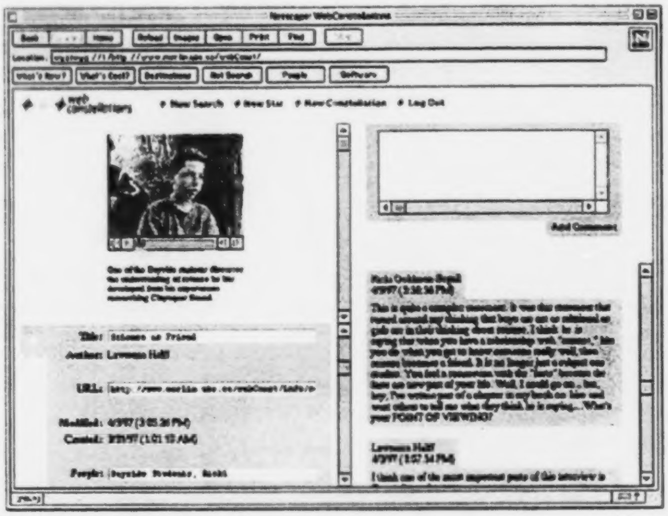

Figure 1: A Star in Web Constellations

Web Constellations system runs on a Web server, which allows researchers to access this system from any machine in any location provided thay have a reasonably fast connection to the Internet (depending on the kind of data being analysed) and a browser which supports JavaScript 1.1 or better. Researchers don't have to worry about saving their work to their own system or sending updated fiels to colleagues. While the actual database program runs in one server location, the data referred to by the stars can exist anywhere on the internet. This means that distributed research teams can make their data available for analysis as quickly as it can be made available as a file on their web server; and heavy data loads can be distributed amoung several locations.

As a system to enable collaborative storyreading, making, and telling, the customized version of Web Constalltions for the book will allow a more limited and directed set of features, which will focus on data interpretation and presentation. Throughout the book readers will encounter pages with video strips on them, showing frames captured from the source video discussed on that page or in that section. They can then enter the address of our website followed by a slash and the page number as a URL in their browser, and they will be shown the video clip within the custom Web Constellations environment. From within this environment, they can read other peoples annotations of that video clip and then add their own. They can still use the search function or an online index to locate other video clips and gather them into constellations, building their own narratives. These narratives themselves can then be further annotated by their authors and other readers who are

entering this environment and participating in the processes of reading, making, and telling. This digital environment not only blurs the authors and readers roles in a very concerete way, it facilitates the development of a global community of reader/authors.

Outcomes

Three outcomes from this book/Web site template using Web Constellations seem to be emerging as we forge on with our design process: (1) digital-data-capture with various media facilitates on-going collaborative access and analysis to those data; (2) the methods of working with data on the Web include "data-mining" and data-linking in ways that further "mechanize" the research process without loosing the storytelling nature of the endeavor; and, (3) the scope of knowledge-sharing include the possibility of greater community building within both the research community and the broader educational community.

(1) Digital Data Capture: The Web for Ethnographic Story-Making

In text-based ethnographic approaches, fieldnotes become constructed into text stories or case studies according to well-known traditions of storytelling and storyreading. But digital video "fieldnotes" living on the net can be manipulated into a range of configurations by multiple "authors" and then reconstituted into unrecognizable video bits and bites. They can be retold as portraits. (And, we forsee, they will be able to take on personae (Stone, 1996; Turkle, 1996) that were never ascribed by the author to these digital "creatures.") At each point, new layers of interpretation are added by selecting and cutting away from a whole or adding new materials to build an artifact. With the addition of intelligent agents to these creatures, they could begin to function for their authors' purposes (Sheeth and Maes, 1993; Davenport, 1996; Negroponte, 1996) as stories are built by multiple authors, if we decide to continue in this direction.

Using the Web for ethnographic investigation, there is the problem of adding complexity that will need to be entangled over the coming years. How will we, as a community of inquiry, be able to make meaning of these digital events? Moreover, each time the representation media form changes, e.g., text to video or video to networked video on the Web, another layer of interpretation and complexity is added. In the multimedia ethnographies Goldman-Segall has conducted in two school sites (Goldman-Segall, 1990 & 1997), layers of interpretations have been added by multiple users, including those persons who are being videotaped. As we watch others view these portraits, interpretations change further. The process of mining one's own data is endless, recursive and even exhausting in it conceptual and operational open-endedness. However, with tools that enable greater scene building, the organizational integrity can be maintained without loosing the flexibility.

Networked digital video portraits enable the viewer to virtually "be there" in situ and interact with the people being described as the research is being conducted. Is this the end of ethnography as we know it, and the

BEST COPY AVAILABLE

beginning of a form of knowing others and "being with" others that includes the researcher and the viewer as actors in an evolving story?

(2) Digital Data Manipulation: The Web and Intelligent Agents

Utilizing the visions afforded by the information highway, we see extensive implications as educational researchers become increasingly wired, doing more of their knowledge-work in a networked space, and ultimately augmenting the data landscape of the human sciences. We situate the research community as members of a vast Web of interconnected researchers, constantly being fed by new data, continuously generating new connections, as they search, clip, and paste their way through research databases, adding further layers of experience-into-data and data-into-experience.

Digital data analysis tools have a serious consequence for the human sciences in the age of information technology — the question of what counts as knowledge in relation to what is emerging as an automated, global hyper-networked body of data, regulated and, perhaps generated through recombinant algorithms, by intelligent agents. What happens to distinctions of representation, authenticity, and validity, of data, information, and knowledge? What becomes of the researcher as data-mediator and data-constructor? These questions seem to be paramount to any building of an inclusive research framework. Questions that, we believe, should be asked by our community before they are answered by the manufacturers of technologies. It is the responsibility of researchers, whose search for constructing knowledge bases are critical to the well-being of many disciplinary and increasingly multi-disciplinary fields of inquiry, to explore these questions as a community.

In short, in building our framework for research, we have attempted, in this paper, to set one template in place that demonstrates the process of transforming "data" or "information" into knowledges and theories, thereby facilitating the construction of a greater variety of knowledge frames. We see this as a deliberate attempt to understand and take greater control of the new research environments afforded by the Web. We seek to establish a forum for exploring alternative paradigms to the specter of increasing automation of the research process. We are developing experimental sites for experimenting with new levels of engagement in the data and analysis process represented by *Points of Viewing Children's Thinking*. We want to explore the epistemological prospects of knowledge-building as a historical process that encompasses earlier technologies of the book, type, library, encyclopedia, and database (Mumford, 1934; Neill, 1995). At issue are the ways in which we assemble knowledge as a definition of how we engage the world. Rather than succumbing to the forms of technological determinism found in the work of those who, like Neil Postman (1992) and Ursula Franklin (1990), would warn of us of the dangers ahead to our humanity, we feel the important task is to build prototypes and models of different ways *being with technology*, of using it to realize what we want and do not want of the world. On building those prototypes and models, which is work currently underway, the next step will be to engage the academic community in exploring through an interactive Website, the look and feel, the potential value and danger, and the range of options sparked by this approach to collaborative research settings.

(3) The Scope of Knowledge-Sharing.

One of the principal outcomes of this work will be to propose a way of responding to new technologies that will full take advantage of Web resources to create innovative forums of engagement and response. The line between sharing and building knowledge will be blurred. Beginning with the original prototypes and models that are now being mounted on the Web, participants will be invited to actively shape the knowledge environment, propose alternative settings and structures, and collaborate on research and reflection in how these new forms operate in extending the nature of the book, the mediation of data, and the automation of research processes. The intent is not to capture the results of the collaboration, but to trace the collaborative process as it creates an intersection for knowledge sharing and constructing. The sharing, then, represents a reflective cycle that learns from the positive and negative possibilities of these new environments, while users are actively engaged in building new models and perspectives. What begins with the traditional format of the book in this project, namely Goldman-Segall's *Points of Viewing Children's Thinking*, becomes its own historical journey across the media, disciplinary and genre boundaries in what could be posed as a collaborative epistemological adventure.

Real-Life Education and Training in Virtual Networks

Matti Hämäläinen and Erkki Rämö
Media Technology Program
Espoo-Vantaa Institute of Technology (EVITech)
Vanha maantie 6, FIN-02600 Espoo, Finland
mattih@evitech.fi, erkkir@evitech.fi

Abstract: In engineering education it is important to provide the students a possibility to become involved in "real life" development projects. The infrastructure for the production, delivery and presentation of network-based learning has matured to a stage, where it has become viable to involve distributed teams of students in the development of electronic course materials. To provide a conceptual basis for such development activities, we have devised a framework for the production, delivery and presentation of network-based courses. In addition to the framework we describe a few projects illustrating our early experiments in how the work of distributed teams acting as "virtual companies" can be organized in the development of educational and training products.

1 Introduction

The novelty of the medium and the technological capabilities can not justify development of network-based courses anymore. To be successful in the future, we need to take a product view of network-based education, where the criteria for evaluating learning products (e.g. electronic courses) include educational validity, cost factors, and the ability to meet the specific needs of customers. The educational evaluation includes such factors as learning outcomes and instructional models; the cost factors include production, delivery and presentation costs per unit delivered. In many cases it is also increasingly important to be able to deliver specifically tailored education at the "point-of-need". We need to provide customized on-demand learning based on systems that support cost-efficient distributed production and delivery of education.

Traditionally education and training have been institutionalized and tied to physical locations. The network-based models provide flexibility in time and space but are often still replicating the conventional educational structures. However, the new medium makes it possible to further dilute the boundaries between the different modes of education and the different providers and customers of learning. New forms of co-operation and collaborative alliances can be formed between educational institutions, training companies, in-house training departments and product vendors. Together they operate as "virtual companies", where each partner contributes their own special expertise to the production of the course.

In this paper we first present a conceptual framework for network-based courses, that we have been using for guiding the design and development process. Thereafter we propose a product view of education for the creation of "electronic markets for learning" to encourage re-use of educational materials but also to provide appropriate incentives and rewards to the providers involved. Finally, we describe some actual projects, in which we have applied the framework and also started to develop the notion of "virtual companies" in collaborative projects between educational institutions and industry, in the development of education and training products.

2 A Framework for Network-Based Education

The explosive supply of educational resources on the Internet combined with the availability of powerful tools for information publishing, multimedia, and for collaboration across distances are useful building blocks for network-based courses. However, to make good use of them, there is a need for comprehensive design and delivery frameworks for cost-efficient and effective electronic course production, delivery and presentation. These frameworks should help in integrating the different modes of learning and provide guidance for the implementation of network-based course production and learning systems. Also, they should support the revision of educational paradigms [Agogino & Wood 94],[Hämäläinen 96]) enabled and furthered by appropriate use of information technology.

One of the key objectives of the two recent international projects that EVITech is involved in, Project CODE and ARIADNE, is to address the cost-efficiency of education provision. Project CODE was initiated in June 1994 as an international coalition among three institutions sharing a vision of student-centered flexible learning as enabled by the convergence of information technology: Espoo-Vantaa Institute of Technology (EVITech) in Finland (co-ordinator), Microelectronics Educational Development Centre (MEDC) in Scotland and the Center for Information Systems Management at the University of Texas at Austin (UT/CISM) in the USA (project overview is available at: *http://www.code.evitech.fi*). ARIADNE - Alliance of Remote Instructional Authoring & Distribution Networks for Europe - is a research and technology development (RTD) project in the "Telematics for Education and Training" sector of the 4th Framework Program for R&D of the European Union. Description of the project and full list of partners is available at: *http://ariadne.unil.ch*. ARIADNE project focuses on tools and methodologies for producing, managing and reusing computer-based pedagogical elements and telematics supported training curricula. Validation of the project's concepts is due to take place in various academic and corporate sites across Europe. In CODE the objectives are similar but more explicitly focusing on supporting specific learning approaches (resource-based and collaborative learning) and on customer-driven production and delivery of education and training (see [Hämäläinen 96] and [Hämäläinen et al. 96]).

One of the most striking features of the current educational systems is the enormous duplicated effort that goes into the production and presentation of the same courses in thousands of locations with marginal reuse or sharing of efforts. To address these problems the learners' and course providers' work is organized around "pedagogical knowledge pools" [Forte et al. 96] or "course material repositories" (in CODE) combined with appropriate submission, retrieval, sharing, reuse and course composition mechanisms. In the following we describe the CODE model and tools in more detail.

2.1 Learner's View

The learning approaches that are explicitly supported by the CODE model are resource-based learning and collaborative learning. These approaches are consistent with the needs of customized on-demand education and have been demonstrated to work well also in network-based distance learning courses ([Alexander 94] and [Dorairaju et al. 94]). The course delivery consists of the following elements which are accessible via the learning environment that provides the learner an interface to various work and resource spaces as illustrated in Figure 1:

- *electronic books:* course materials (textbooks and learning tools) available either locally or remotely and customized to the needs of homogeneous groups of learners
- *virtual library:* relevant external/internal information resources often linked to course materials
- *study tools:* applications designed to assist in the learning process
- *collaboration tools:* applications and procedures for collaborative work enabling asynchronous and synchronous communication between students and instructors as well as among students
- *assessment and feedback tools* for self-evaluation as well as for instructor assessment and feedback

The learning environment aims at supporting both on-line and off-line learning by integrating asynchronous and synchronous multimedia communication with electronic learning resources on the local workstation and on the Internet [Watabe et al. 95]. The learning resources are available in the *resource space* and consist both of course materials (i.e., "electronic books") and of external information resources available on the network (i.e. "virtual library"). The course materials have been composed and customized for the course being presented while the vast information resources and services accessible via the network are provided "as is" as reference materials. Some of the relevant external resources may be linked to the course materials while others can be found by search mechanisms used by the learners. For improving access and reducing communication costs it is in many cases essential to make the bulk of the course materials also available at learner's local workstation. This may happen either by delivering a CD-ROM or providing mechanisms for batch delivery from the network server to the local workstation still retaining the material's original structure and functionality as much as possible.

Figure 1: Learner's View of a Course in the CODE Environment

Course production and customization is based on course material repositories, where learning material elements are represented as structured documents using standard document encoding languages (SGML, and HTML in particular). Support for distribution of the production and presentation of courses and methods to facilitate reuse and customization of the material are among the main objectives. A number of prototype implementations of tools and systems have been developed on top of the WWW, to enable testing of the feasibility of the model proposed. Among them are:

- *QuizTool*, an exam and feedback system based on SGML-encoded exam and answer files. It includes tools to support exam authoring in the MSWord environment, and alternative exam presentation and analysis systems. These are implemented on the Web-server as CGI-programs for on-line use, and as Java-applications for both on-line and off-line use (e.g. for CD-ROM based material)
- *DiscourseWeb*, a structured discourse and annotation system allowing hierarchical annotation chains on WWW pages (to help in integrating resource-based and collaborative learning)
- *WebCourser*, a prototype for electronic course broker combining a course material repository and a customization system based on customer/learner profiles and course element descriptors.

2.2 Towards Education Brokerages

Actually, as one of the largest "information industries" in the world, education has the potential to be a key application in electronic commerce. As we move further into network-based delivery and presentation of courses it will become necessary to start developing electronic intermediaries or electronic course brokers that help in composing and delivering courses appropriate for the customers. These education brokers will operate on the "electronic markets for learning" to provide value-adding services both for the customers and suppliers of education [Hämäläinen et al. 96].

The conceptual framework that we have described above maps naturally to the Internet resources and Internet tools. By adding services on top of the current tools, in particular by extending the functionality of the WWW servers (via CGI) and clients (via Java-applets) it has become possible to implement a course broker as a set of software processes [Hämäläinen et al. 96]. In the broker model the delivery is based on customer order and the necessary transactions thereafter are coordinated by the broker. The electronic course broker is actually an example of electronic commerce applications [Kalakota & Whinston 96]. An Internet-based implementation of the course broker model (WebCourser) is currently being developed at EVITech. The task of the course broker is to compose a course, or set of alternatives, that match the needs and profile information of the customer. The implementation model based on practical document management and information retrieval techniques is illustrated in Figure 2. The retrieval of potential candidates for course elements is done automatically by matching the customer need and profile data with the course element header data. The actual course composition will require the user to make the final choices as well as the final structuring and fine tuning of the course.

3 Real-Life Cases

3.1 Computing English Updated - An Online Course for Language Learning

We started collaboration with Edita Oy in 1995. Edita is a leading company applying electronic publishing methods in Finland. They have developed SGML and HTML-based publishing for several years. The first product was the publishing of the multimedia book *Computing English Updated* on the WWW. The text and images of the book were converted from PageMaker format to HTML. The book has a lot of hypertext links to glossary items. After completing each unit the student can take the exercise session. The functionality of the exercise is planned according to the CODE model. There are free text answers, multiple selections and matching questions. The contents of the accompanying audio cassette was digitized and linked to the document. With a multimedia workstation the student can listen to narration and then answer the questions. All the answers are sent by email to the teacher. The student can also get the correct answers at his will. A demo of the product can be found in *http://www.edita.fi/edi/pankki/compeng_nayte/unit6.html.*

3.2 Learning Infobahn (LIB)

A new international three years co-operation project *Learning Infobahn* (LIB) has been started at the beginning of 1996 together with three Finnish polytechnics (Espoo-Vantaa, Satakunta and Lahti), several universities and polytechnics in the USA and Germany, and SME companies in Finland. The project belongs to the re-industrialization program of the Finnish National Board of Education. The aim of the project is to:

- integrate art and technology in its functions
- start common pilot projects applying communications technology
- support the commercialization of communication products in SME sector
- develop the curricula of media polytechnics according to industrial needs
- acquire tools and contents for Learning Infobahn
- stimulate collaboration between USA, Germany and Finland by applying new communication technology
- support entrepreneurship of the students of media technology

BEST COPY AVAILABLE

During the first year of the project two new SME multimedia projects have been launched: Development of a CD-ROM/WWW publication of the tourist services of Southern Finland (Human Capital Investment Inc) and electronic publishing of the National Biography of Finland (General Media Carnac). In both projects a virtual enterprise of about ten students was organized in a couple of weeks for developing demanding commercial multimedia applications. The next step we need to do, is to establish appropriate models and methods for project execution in such distributed teams.

4 Conclusions

New models of course production, delivery and presentation are needed to guide the education providers in implementing cost-efficient and also effective learning systems. With network-based delivery and presentation of courses, we can start envisioning education as one area of electronic commerce, where educational products can be composed from a number of suppliers, each focusing on their special expertise, thus forming a "virtual company" for the production and delivery process. The building blocks would include the repositories and broker services described above, combined with systems to handle copyrights, licensing, authentication, security, and electronic payments. Despite of all the administrative and technical obstacles, this may be closer to reality than we are willing to admit in the academic world.

We have found it useful to develop and further enhance the framework described at the beginning, to provide a conceptual basis for the "real life" collaboration projects in the area of network-based learning. These projects also are examples of our early steps in experimenting how the work of distributed teams in the "virtual companies" could be organized in the development of educational and training products. Only by trying out the ideas in industrial use the feasibility of the approach can be verified. For the primary mission of EVITech, the provision of high quality engineering education, we see these projects essential as they provide the students a possibility to become involved in real development projects, often already at an early stage of their studies. Much of the work described above has only been possible due to the commitment and efforts of the students involved in implementation of these systems.

Distributed team-work is already a well established and successful method in projects. However, we are now approaching the stage where starting a new project can involve the creation of a "virtual enterprise" for the design and execution of the project. The production, delivery and presentation models have matured to the level, where we can start adapting them to a variety of educational settings. The next possible course of action is to organize the produced content as elements of educational products, combine them with elements supplied by other material providers, and establish an education brokerage that has potential to sustain and develop its operations via appropriate licensing and payments schemes.

Acknowledgements

We would like to thank our colleagues Ms. Seija Ristimäki and Mr. Veli-Pekka Liflander, and our collaborators in the various projects for developing the ideas and designs for customized on-demand learning on the Internet, including Prof. Andrew B. Whinston, Zhangxi Lin and Svetlana Vishik at the University of Texas at Austin, Prof. Kazuo Watabe at the University of Shizuoka, and Prof. Karen Lemone at Worcester Polytechnic Institute (visiting EVITech 95/96), as well as many others involved. The implementation of the various CODE tools has been carried by our students at EVITech and UT Austin, and by the exchange students of the Middlesex University, the South Bank University (London), and the Hogeschool van Amsterdam. Also, the co-operation of our numerous industrial partners is highly appreciated as well as the devoting attitude of our students in all the projects mentioned. The ARIADNE project partners have made relevant contributions to the development of the re-use ideas of educational materials.

Researching media and learning: a qualitative approach to data collection

Ian Hart ,
Centre for Media Resources,
The University of Hong Kong
ianhart@hku.hk

ABSTRACT: In qualitative research a wide variety of data formats is available to the researcher, including questionnaires, interview transcripts, videotapes, computer output, concept maps, artifacts, etc. This rich, unstructured data is not easy to handle and presents particular problems with indexing and analyzing; the potential outcomes, however, are complex and fascinating with inbuilt possibiltiies for triangulation. The paper describes one approach to the collection of unstructured data.

THE ISSUE

This paper describes a qualitative approach to the study of cognitive construction when using computers in a problem-based university course.

The students were in the professional years of an Architecture degree undertaking a unit called Building Systems in which they were required to work collaboratively on the development of 3D computer models. The course represented a significant change in teaching strategy and the accrediting body (Hon Kong Institute of Architects) required reassurance that this approach was as valid as the previous lecture-tutorial-project method. The HKIA suggested that the Department set up a comparative study in which an experimental group undertook the problem-based course and a control group followed the old course. This approach was not possible as there were insufficient resources to mount both courses. In any case, bearing in mind Clark's (Clark, 1983; Clark, 1994) meta-analyses of media comparison research, such a study would probably have demonstrated "no significant difference". (This is actually what the HKIA would have liked to hear!)

The teaching staff were convinced that the problem-based method would lead to more effective, though different types of learning and were interested in observing how students would use the sophisticated computer tools to construct knowledge. Therefore, rather than set up a laboratory-style, experimental study and devise a hypothesis, or a "no significant difference" null hypothesis, the researchers set themselves an open-ended question:

> *In a problem-based, computer intensive learning environment, what is the nature of the interaction between student characteristic, computers and cognition?*

It was decided to use a qualitative, data-driven approach: to observe the progress of the unit, to record what happened, to allow the issues to emerge from the data, then to attempt to construct some theoretical insights about the "nature of the interactions." The data were to be organized using the qualitative research tool NUD*IST (Non-numeric Unstructured Data - Indexing, Searching & Theory-building)

In this paper I will describe the range of unstructured data which was collected for this study and indicate briefly how it was used in the analysis and theory-building stage of the evaluative research.

THE STUDY

The main part of the study took place over a four month semester . Follow-up interviews were conducted in the following semester with eleven of the original students who continued with Building Systems II, and finally one year later, at the end of the degree program, all the students were interviewed again and given a follow-up PFNet.

The research question dictates that three types of data needed to be collected:

A) data relating to student characteristics (SPQ and entry level computer knowledge test)
B) data relating to the interaction between students and computers (mental models of the system and PFNets)
C) data related to cognitive construction (videotapes, interviews and artifacts)

(A) STUDENT CHARACTERISTICS

The profile data was collected in the first week of term. Two indicators were used: approach to study as measured by the Study Process Questionnaire and a test of entry-level knowledge in 3D computer modelling.

(I) APPROACH TO STUDY

The Study Process Questionnaire is the Hong Kong tertiary version of a questionnaire developed by Biggs (1991). It provides a profile of each student according to his/her predispositions to learning on three scales: Surface motive & strategy, Deep motive & strategy and Achieving motive & strategy. Students were tested in the first week of the term.

Figure 1 illustrates two students SPQ profiles, graphed as deviations from Biggs' Hong Kong university student norms (the 'normal' range is 3-7): Figure 1a shows a student who is within the normal range on both surface and deep approaches but appears to lack ambition; whereas the student in Figure 1b has well developed strategies for success.

Figure 1: SPQ scores as deviations from Biggs' H.4. norm

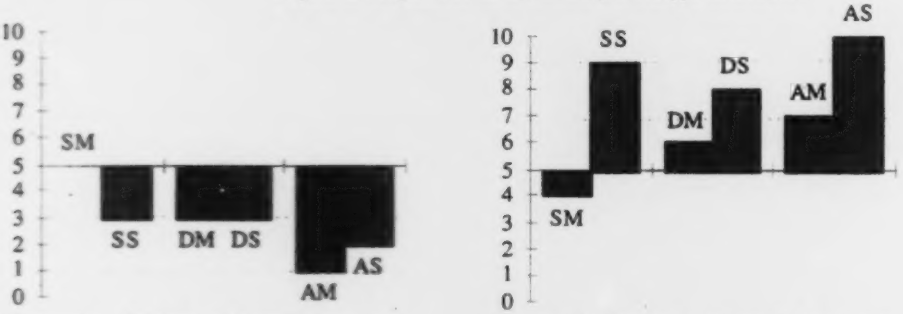

Figure 1a: Student with average to low scores on all scales

Figure 1b: Student with well-developed strategies

(II) COMPUTING KNOWLEDGE: MIND MAPS

Students were tested at the beginning of the unit on their computing knowledge. They were asked to create a 3D model in AutoCAD and describe what they were doing as they worked. The sessions were video- and audio-taped and then mind-mapped using Buzan's (1993) technique.

Figure 2: Mind maps of computing knowledge

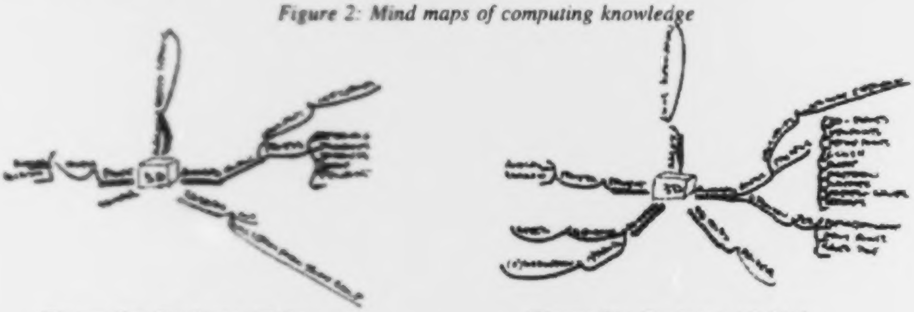

Figure 2a: Student with low declarative and contextual knowledge

Figure 2b: Student with high declarative knowledge of AutoCAD and contextual knowledge of computing.

Mind mapping involves identifying key concepts, looking for links between them, and developing these links into a branching structure from a central concept. Figure 2 illustrates two mind maps derived from the demonstrations of 3D computer modelling: the 3 o'clock branch divides into categories of knowledge about AutoCAD; 5 o'clock represents knowledge of other computer programs, such as 3D Studio, Photostyler and AME; 7 o'clock lists benefits of computer modelling in architecture; 9 o'clock categorizes ways in which computing will be used in the coming project; and the 12 o'clock branch is for metacognitive issues and insights on learning.

(B) INTERACTIONS BETWEEN STUDENTS AND COMPUTER

(I) MENTAL MODELS OF THE SERVER

Some weeks into the study the research team noticed that students were having great difficulty saving and finding their files. The researchers asked the students to draw a representation of their mental model of the computer system. The four representative images in Figure 3 clearly illustrate why some students were having difficulty.

Figure 3a is a reasonably accurate hierarchical model of the file structure produced by one of the group leaders, indicating that she had a clear picture of how files were organized on the server; Figure 3b is an architectural style of drawing showing five workstations and the links between them, the hidden computer network is described as being "like bamboo structure underground"; Figure 3c is a picture of the X-windows screen when the student first turns on the computer; and Figure 3d is a whimsical attempt to anthropomorphize the computer into a representation of a human brain, complete with eyes (the files are shown in the left frontal lobe!).

(II) STRUCTURAL KNOWLEDGE: PFNETS FOR CONCEPT MAPPING

Pathfinder networks (PFNets) result from semantic association tests in which subjects are asked to rank the "relatedness" of pairs of concepts. The resulting output is a graphic representation of the subject's concept map of a group of terms. It is a technique more commonly used in market research than learning research, but it proved to be a valuable tool, particularly when followed up by an interview in which the student was asked to interpret the resulting "network". (For further information on PFNets, see Schvaneveldt (1990)) The software used to produced the PFNets was KNOT.

Figure 4c: "Branching" pattern

Figure 4c: "Line" pattern

Students were asked to do a semantic comparison test using 11 words which had been distilled from earlier interviews and had all become low-level nodes in the NUD*IST data base (*me, my group, computer, software, presentation, calculation, modelling, creative, research, learning, memory*). The aim of the exercise was to see how closely students related computers to themselves and their group as well as to concepts such as creativity and learning. Figure 4 illustrates four characteristic patterns from this exercise which appear to indicate the level of structural integration of domain (architectural) and computing knowledge.

The four patterns illustrated in Figure 4 show a progression of relatedness of concepts. In 4a all concepts are related equally, indicating either an excessively deep approach or the student's inability to make up her mind; in 4b everything is related to one central concept, in this case *computing*; 4c shows a well-structured branching pattern in which "personal" concepts (*me, learning, creativity*, etc.) are linked to computing concepts through the *project*; 4d is from a student who displayed a predominantly surface approach to learning - the single linking concept here is *memory* - note that *research* is at the maximum distance from *learning*.

(C) LEARNING

The teaching staff in Architecture saw learning as a constructivist process, the final outcome of which was to be the interactive 3D model. The evaluation of the learning experience, therefore, could not be accomplished using tests of declarative or even procedural knowledge. The team collected data on student progress continuously over the course of the term, using mixture of observation, interviews and artifact collection.

(I) VIDEO OBSERVATION

Class meetings and project demonstrations were covered on videotape using a Sony Video 8 Handicam with 12x zoom lens and built-in and extension microphones. Two types of set-up were used: hand-held (which proved technically difficult and was mainly employed for reference only) and off-screen recording incorporating picture-in-picture.

The most satisfactory result was obtained by recording directly from the SGI video port through a video converter onto the Handicam and combining this signal with the image from a fixed camera using a "picture-in-picture" device. The connection diagram is illustrated in Figure 5.

Figure 5: The video observation system

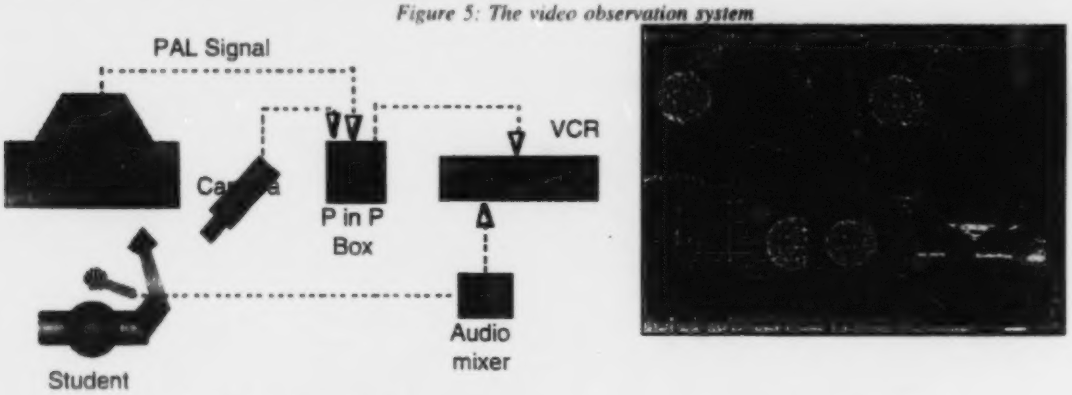

Figure 5a: Connection diagram

Figure 5b: Output

The *p-in-p* system was adjusted so that the computer screen comprised the main image and an image of the student was superimposed in one of the four corners. Figure 5b shows the student's image positioned at the lower right of the frame as this is normally the least used area of the screen in graphic work.

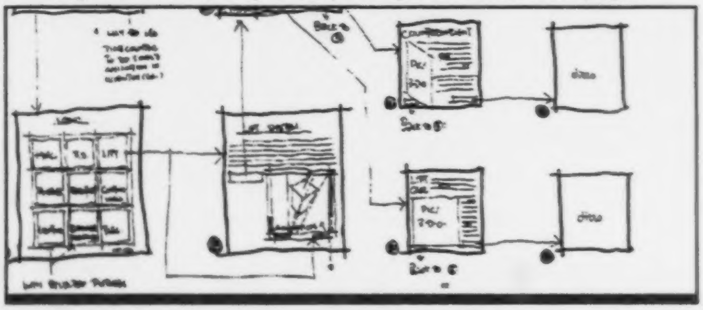
(II) TRANSCRIPTIONS

The videotapes were logged using a computer program called "C-Video", which enables the replay of the Sony Handicam to be controlled directly from the Macintosh numerical keypad by means of a cable between the computer's serial port and the LANC remote control plug on the Handicam. C-Video produces a text file which can be introduced directly into the NUD*IST data base, and enables time stamping of the transcript. The later interviews as well as interviews with teaching staff were recorded using audio only. The interviews were conducted in an office off the laboratory or in a staff office and were fairly informal and open-ended although a list of questions had always been prepared and were always asked — though not necessarily in the same order.

(III) ARTIFACTS

In addition to videotapes of students at work and transcriptions of interviews and demonstrations, the researchers collected media such as students' preliminary sketches, storyboards, etc. as well as scans, photographs, videotapes, screen captures, audiotapes, mind maps, etc. As much as possible of this material was converted into electronic form and stored on disk for easy reference. E.g. Figure 5b is one of a set of screen captures, or "key frames" made to accompany transcripts of videotaped sessions. Figure 6 is a detail from a computer scan of a preliminary storyboard.

Figure 6: Detail from first storyboard for the Maintenance project



The most important artifacts, of course, are the completed multimedia projects, impossible to illustrate in a printed paper. They are, however, available for inspection at the HKU Department of Architecture's World Wide Web site: http://arch/hku/hk (Student Projects/ Building Systems directories)

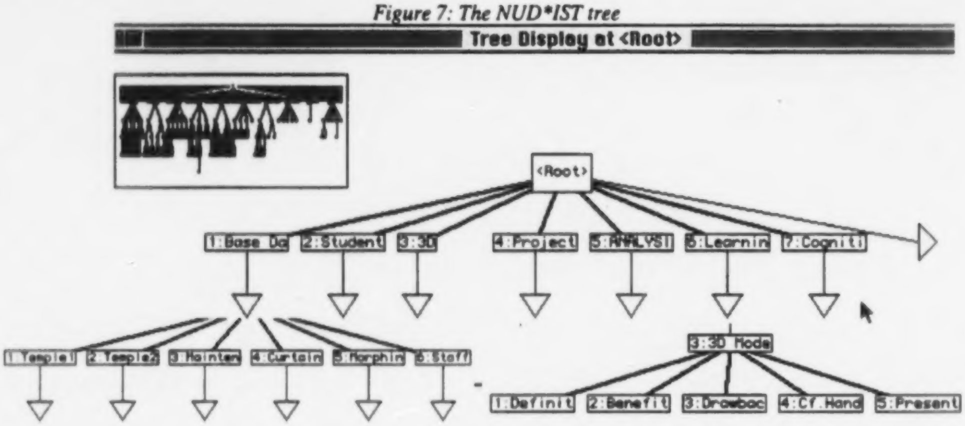
ANALYSIS

QSR NUD*IST is computer software for qualitative researchers which facilitates the handling of textual (on-line) and graphical, video and statistical (off-line) data. It provides an environment in which the researcher can create, manage and explore ideas and categories derived from the data. An example of one of the NUD*IST interfaces (the tree display) is illustrated in Figure 7

*Figure 7: The NUD*IST tree*



NUD*IST was the primary cognitive tool used to organize the data. Documents are imported into the program where they can be explored, creating categories at which text units are coded. They can then be searched for patterns in coding, from which new codes can be developed. Using the various interfaces, the researcher can clarify ideas, discover themes, construct and test theories, create memos about the data and finally generate reports including text extracts, coding patterns and statistical summaries.

There is insufficient space in this paper to go into the process of analysis and theory building which was followed in this project. Detailed discussion of the qualitative research issues is available in (Hart, 1996) and (Hart, Will, & Bradford, 1997).

In summary, the project demonstrated that:

- the problem-based, computer-intensive curriculum promoted a "deep" approach to learning,
- students valued the situated nature of the task,
- for the more successful students, the computer system was a cognitive tool, which they manipulated consciously, and
- the outcomes (the projects) demonstrated the development of complex cognitive constructions

The project was also able to point to aspects of teaching which needed to be more strongly reinforced, such as:

- the encouragement of metacognitive knowledge,
- the acceptance and utilization of distributed cognition, and
- the need to teach and reinforce contextual (in contrast to declarative and procedural) knowledge.

Adaptive Testing and Multimedia for Vocational Guidance

Joachim Hasebrook [1] & Markus Gremm [2]

Introduction

Despite the importance of career decisions, people often feel a lack of competence in career decision making and do not know how to collect and evaluate appropriate informations. Recent tendencies of the job market force young adults to accquire optimal qualification in order to get adequate jobs. Therefore, improvements in pedagogical and psychological counselling methods are required. Professional and semi-professional software is at hand which promise to support career counseling processes. In what follows, we are describing the development and evaluation of a multimedia CD-ROM and an adaptive testing facility dedicated to provide vocational guidance. In this paper, we want to show how multimedia and individual adaptation can be used to support career decision making by providing vocational guidance.

Learning with multimedia

As of today, empirical research has not been able to support the enthusiastic visions of multimedia. In their most recent meta-analysis, Chen-Lin and James Kulik (1991) examined 248 research studies about computer-supported learning. 150 studies failed to show any significant effects. The other studies showed only a slight advantage of multimedia over textbooks or lectures: Error rates of simple retention tests were reduced between 5% to 15% ($Eta^2=.15$), problem solving was hardly enhanced, and study time was reduced between 20% to 70%, with an average reduction of time about 30% ($Eta^2=.35$). Considering all studies included into the meta-analysis, multimedia produced only a small effect ($Eta^2<.01$; Hasebrook, 1995a).

Although, multimedia seems to save some time and reduce simple learning errors, it has not been found be very effective as a problem solving tool. Clark and Craig (1992) investigated several meta-analysis, including the analysis by Kulik and Kulik (1991; Kulik, Bangert-Downs & Williams, 1983; Kulik, Kulik & Cohen, 1980). Their findings also indicate that multimedia applications are not overly effective. Most of the positive effects derive from general organizational and instructional changes in the learning environment.

Fortunately, however, there are also some promising studies showing that multimedia could potentially facilitate the learning processes. The Software Publishers Association (1995) reviewed the effect of instructional technologies in 133 school studies from 1990 to 1994. They found that there were better test results, an increase in self-reliance, and a closer interaction between students and teachers. Similarly, Boettcher (1993) collected "101 success stories in higher education" in his book. Thus, multimedia can help people to enhance communication, motivation, and self-efficacy. This, however, does not necessarily lead to better learning rates but it could potentially facilitate career decision making.

447

The case of adadaptation

Duchastel (1992, pg. 69) claims: "Adaptation is essence of what is known as pedagogical knowledge". Many researchers aim to make their multimedia systems more adaptive – and therefore more "pedagogical" (e.g. Cox & Brna, 1995). Expert systems and Intelligent Tutoring Systems (ITS) adapt to the learner´s demands, abilities, and knowledge – especially in subjects which can be described in formal logics (Bastien, 1992). There is an increasing number of adaptive computer programs which is equipped with media like videos and photographs. Although there are no clear cut borders between expert systems, ITS, and other adaptive multimedia systems, Clancey (1987) divides expert system from ITS by two distinct features: (1) The knowlegde base of an ITS tries to model human knowledge, an expert system does not. (2) Expert systems are not equipped to support learning processes, because they do not explain their rule or knowledge bases and the inferences drawn from that bases. As of today, a diverse spectrum of techniques, approaches, and philosophies impeds the progress in intelligent learning environments (Self, 1992). There are promising results, however, supporting positive effects of intelligent learning environments teaching mathematics and programming (e.g. Weber, 1995). In general, effects of adaptation and system-controlled tutoring have been small or medium sized, yet (e.g. Rosenberg, 1990; Kelley, 1988).

Although knowledge based systems are well established tools, there are hardly any implementations of sytems for vocational diagnosing and counseling (Ueckert, 1995). Psychological testing procedures including computer-supported diagnosis are used to conduct aptitude tests in personnel selection (e.g. Sweetland & Keyer, 1984; Funke, 1993), to implement adaptive testing optimizing economy and performance of personality, aptitude, and ability tests (e.g. Cronbach & Gleser, 1965; Bennett, 1993), and to perform decision analysis applied to management diagnostics (Nagel, 1993). But there are hardly any computer-based, psychological testing procedures adressing vocational guidance. This does not mean, however, that there are no software products available: Counseling software guides list 200 programs, approximately, that are designed to support self assessment, job finding, and job keeping (Walz, Bleuer & Maze, 1989; Katz, 1993). About 100 titles incorporate surveys or self-testing facilities in order to provide the user with information about his or her career alternatives and prospects of career satisfaction.

Software to improve vocational guidance

Career decision making can be described as a system consisting of highly interactive components (Katz, 1993; Kerka, 1987):

- *Options:* They define what the decision is about, e.g. apply for a job or another, enroll in one educational program or another, accept or reject a job offer.
- *Persons:* This refers to the self-concept of the decision maker but also to the interaction with other relevant persons.
- *Environments:* Of course the social and the cultural contexts are important. Furthermore, job characteristics like actions, work load, independence, income, and security play an important role for the decision maker.
- *Processes:* This term refers to the ability and the actual course of decisions making.
- *Outcomes:* The outcomes of a decision process in terms of success, satisfaction, and efficiency may serve as an input for a new career decision making process.

All this components or dimensions are considered to be parts of a decision process that aims to minimize the difference between qualification, preferences, and requirements. Variations in the importance attached to each dimension by different individuals means that they can come up with different optimal outcomes (Holland, 1985; Katz, 1993). For example, some may especially want job security, high income, work in a main field of interest, and various combinations of such rewards. Career counseling software can support the counseling process in serveral aspects (Bridges, 1989; Kerka, 1987):

- The software can offer both instruction and practice (e.g. interviewing for jobs).
- Some programs have quizzes or exercises allowing an evaluation of career maturity or job hunting skills.
- The program can access information from large databases of job fields or careers.
- A large group of software allows users to answer questions about likes and dislikes and match them to careers.
- Some of this programs takes the repetitive work and tedious jobs away from the counselor, hence, enabling him or her to focus on interactive career counselling.

The most common complaints regarding these programs are (Katz, 1993; Bridges, 1989) poor usability, long response and searching times, a lack of adaptability to the audience, too few or inadequate assessment questions, and a lack of complete and up-to-date information. Based upon this considerations we developed an adaptive testing facility to support career decision making by matching interests and preferences with job characteristics. Additionally, a vocational encyclopaedia was produced to inform the user about relevant job characteristics like actions, work load, income, and so on (Hasebrook & Graßl, 1995). Our testing facility is not designed to mimic the full range of an interpersonal counseling process. Rather, it shall provide the user with a variety of job opportunities which match his or her personal interests and preferences. Figure 1 gives an overview of the system´s components.

Evaluating adaptation

There are several psychological inventories dedicated to measure career development and vocational maturity. One goal was to make valid prognostications of the career development and the vocational success. Most of the studies, however, show essential validity for short-term predicitions, only. Therefore, most investigations focus on enhancing construct validity. High construct validity, however, gives little support to career decision making and vocational guidance (Seifert, 1994). Therefore, we evaluated our adaptive testing facility for its practical validity – that is, how are the system's responses accepted by students and counseling experts. 43 students participated in an experiment to investigate the understanding and acceptance of the information provided by the system. Furthermore, we explore whether the system is able to reconstruct 38 expert's ratings.

We asked the students to rank four different job lists according to their judgement, whether the lists match their vocational interests or not. The students were told that the four lists were generated by four different computer programs. In fact, only one list was calculated by our computer system, three list consisted of random selections. The results show that students are able to judge, whether careers match their individual interests or not (cf. figure 3): They preferred individually calculated job lists compared to random lists ($F[3,122]=11,8$; $p<.001$; $Eta^2=.23$). But they were not able to tell them apart from a list which consists of well-kown jobs which do *not* match their interests (Scheffé $p>.05$). Therefore, the students' jugdements rely on weak criteria (sometimes) leading them to wrong conclusions. This assumption is confirmed by the data displayed in table 1: There are positive correlations between the students' judgements about...

- how well the suggested jobs match their interests,
- how well they know the suggested jobs (based upon concrete informations),
- and how well they can imagine what are typical professionals are doing.

However, there are negative correlations between all these variables and the actucal state of information: The more information the students have got, the less they are willing to accept suggestions – and the less they have got a feeling of knowing. Therefore, information leads to more scepticism and critics which is needed to carefully guide the career decicion making process.

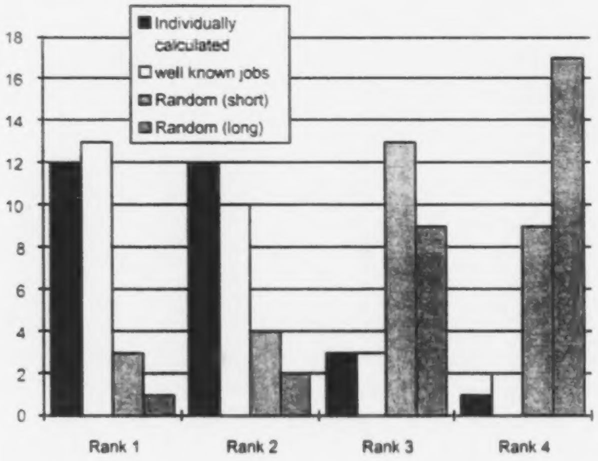

Figure 3: Students prefer individually calculated job lists – but they cannot tell them apart from well known, generally preferred jobs, which do *not* match their interests (n=29).

The system shows a good performance in reconstructing the experts' data – except of one academical career which was not described very clearly: The system correctly identified between 85% and 100% of the experts' ratings (academical career 42%). Adjusted goodness of fit scores (AGF) of a LISREL model were between .81 and .92 (Jöreskog & Sörbom, 1989).

Match			
Know	0,56		
Imagine	0,42	0,58	
Information	-0,49	-0,36	-0,34

Connecting multimedia and adaptation

In a recent study, we tested the influence of the adaptive testing facility and a software video on recall of information and individual acceptance by means of a 2x2 factorial design. The testing facility enabled the participants to enter their vocational interests and to receive a list of suggested jobs and educational programs from a multimedia encyclopedia. Additionally, all participants received the same list of jobs. The subjects were randomly assigned to the two video conditions: One group watched the video before reading further informations, the other group watched the video after having read the informations. The study has two parts: During the learning phase the participants read informations about jobs and educational programs; during the testing phase, all participants completed two surveys: (1) They rated the overall acceptance of the program, its functions, and its informations. (2) They completed a cued-recall task. Table 2 displays summarized scores from these surveys. The results confirm that video enhances acceptances ratings but does not influence recall (F[1,73]=.4; n.s.). Recall is clearly enhanced, however, when studying individualized materials compared to general informations (F[1,73]=13.9; $p<.01$; Eta^2=.16).

Table 2: Acceptance ratings (0=complete rejection, 25=complete acceptance) and cued recall (0=no recall; 25=complete recall) as a function of list of jobs (previously fixed list vs individually generated list) and video (displayed before vs after reading).

	Job			
	Previously fi:		Individually gen	
Watching Video	Before	After	Before	After
Accecptance	10,3	9,5	9,5	8,6
Cued Recall	8,2	6,8	11,5	11,2

Conclusion

Multimedia have potentials to enhance and facilitate career decision making. Most of the recent multimedia systems, however, show small positive effects or none at all. The effective use of multimedia is influenced by many internal and external factors, like motivation, knowledge, mode and contents of media, learning strategies, features of the task, etc. Making multimedia applications effective means to start from the user's perspective: Mostly, this implies to conduct a study about needs and abilities of the users (Hasebrook, 1995b).

Individually generated information clearly supported both acceptance and recall of vocational information. The effects were enhanced, if individual differences in usabilty ratings were taken into consideration. Our findings match other research results indicating that individually adapted informations enhance motivational and learning processes within computer-supported learning environments (Bastien, 1992; Weber, 1995; Cox & Brna, 1995).

Adaptability of the system clearly increases acceptance and performance of the system. But this does not neccessarily mean that one has to bother to make a system "intelligent": It certainly demands any effort to support the in-born intelligence of the user. Multimedia applications should not be designed to provide "something for everyone", but they should provide exactly the type of information that is needed in a particular state of the decision making process.

Telecom and Open Learning - a Challenge to Institutional Co-operation

Harald Haugen, Dept. of Educ. Inform. Science, Stord/Haugesund College, NORWAY, harald.haugen@hsh.no

Bodil Ask, Dept. of Computer Science, Agder College, NORWAY, bodil.ask@hia.no

Abstract: The increasing demand for professional updating and trends towards lifelong learning challenges the flexibility of higher educational institutions. Application of information technology and telecommunication seems to be one way of meeting these requirements. Open and distance learning (ODL) has to be provided for larger audiences than the traditionally registered students. In order to take optimal advantage of the new technologies, co-operation between academic institutions have turned out to be of benefit to all parties involved. Some practical examples and advances in this field will be presented. Experiences referred to are obtained by 4 Norwegian institutions at national level, later expanded to 8 European institutions in an international project. Organisational as well as pedagogical and subject related co-operation have turned out to offer valuable synergy effects, to the benefit of both staff and students involved.

Life Long Learning

1996 was declared the *European year for life long learning*, stating the fact that there is an increasing demand in all walks of life for updating and refreshing of existing knowledge and skills in order to keep abreast with professional and social requirements. Life in the information age and the knowledge society puts new demands on professional roles and performances. The technology itself changes the characteristics of traditional work, it also shifts the required skills for certain operations into completely different levels of understanding or detailed knowledge. Most professionals still tend to postpone the extra effort to embark on traditional continued education or in-service training programmes. The access to life long learning can be simplified by in-service training through the use of computers and electronic networks. European and national initiatives are launched in order to exploit these possibilities.

Cooperation between course providing institutions seems to be a fruitful track for saving efforts and resources. Partners may save much on development costs, administrative systems and infrastructure, and at the same time increase the quality of final products and offers to the target groups.

The role of the teacher or trainer is gradually changing from that of being a knowledge provider and a well of solutions to all problems, into being a guide or adviser for learners to find and choose from the information and instructional material already available. In a society where the amount of available information is growing exponentially, it is becoming increasingly important to assist learners in acquiring skills of information handling. An important part of this is to develop a critical and reflective way of sorting, discriminating and interpreting the information provided. Learners must also be able to turn the acquired information into knowledge and understanding of their immediate surroundings and the challenges facing them.

IT and Telecommunication

Particular requirements are related to new technology as part of new professional roles. ICT is not only a tool and a source of information, it is also in its own right an important part of workmanship and required skills of future citizens. It is accepted that a clerk expecting to maintain his work in these days must know how to apply word processing, and that an accountant will be obsolete if he does not know how to handle computer based accounting systems. It is recognised that a journalist or a history teacher must know how to search in databases for interesting extensions to his lessons on the present situation in the Middle East. It is equally important, however, for a social science or a biology teacher or an environmental adviser to manage system dynamics and simulation models in order to understand or communicate the challenges of local or global pollution.

Telecommunication seems to play an increasingly important role in future society. Networks with increasing capacity, band-width and speed of transfer for large amounts of digitised data, including sound and graphics, are covering greater parts of the world every month. From being a separate technology it is now accelerating its integration into computer and other information technologies, changing the PC from a stand-alone device into a node in a world wide network of information. Large databases are included in the same network and professionals of all kinds are meeting in the virtual space to discuss their problems and points of interest.

Open and Distance Learning (ODL) as a Tool to Cope with New Demands

The ever increasing demand for updated skills and knowledge in different fields makes it impossible to cover it all through traditional educational or training systems. Companies and public institutions have long traditions in arrangement of courses in-house or at hotels etc. when new skills or principles are introduced into their activities. No credits or formal qualifications were attached to most of these courses. It was part of the in-service training offered by the employer and required for updating on tasks to be performed.

An alternative for raising the qualifications of the staff is to let a selected few attend formal education programmes, acquiring new degrees or diplomas. Expenses related to such programmes can be born by the employer, by the professional her-/himself or as a joint agreement between the two parts. Costs are considerable for study programmes running over several years in order to obtain a degree, even in cases where the education or training is provided outside regular working hours.

Distance education has long been a practical way of taking courses and obtaining qualifications. Specialised providers like correspondence schools and open universities have offered thousands and millions of citizens interesting courses of initial and further education. In the age of new ICT it is natural to apply the technology for distribution of learning material. As a consequence of this the importance of distance in the learning process is changing. It is now becoming more essential to talk about *open* learning, possibly combined with learning at a distance into *open and distance learning*, ODL.

The definition of ODL varies according to organisation, structure and possibilities included. In this presentation we will stick to the interpretation where the *openness* is particularly directed to the *open access* of learning material through electronic networks. The *distance* of the students is not of the same importance to us; they may well be regular students inside the institution, staff members or individuals in another part of Europe. The important principle is that university courses, learning material as well as exercises and examinations are available to the learners in their part of the world. With certain restrictions the services should also be available to them when it is required, i.e. asynchronous distribution and availability is the general rule.

ODL makes career training accessible, costs and fixed working hours can be saved and the traditional universities and colleges may be opened to the public for life long learning programmes. The effort for traditional universities in order to change some of their traditional mass lectures and demonstrations into transferable, ICT-based learning material is quite a scary exercise. It may not even be possible or desirable in many cases, in particular subjects or topics. The latter is certainly the case for some of the special aspects, e.g. in training of nurses or in teacher education, where important values can hardly be detached from the human touch. There are, however, lots of topics and courses related to teacher and nurses training that may successfully be offered through ICT based ODL, and where positive results are already observed.

Challenges to Institutional Co-operation

The enormous efforts and resources needed for providing ODL material to new groups of learners simply require that parallel work and development of products should be avoided. All partners will benefit from co-operation instead of competition, exchange of material instead of protection, specialisation of competence instead of covering all fields at every institution, sharing of duties in stead of performing double work. In particular the learners will benefit from the products and facilities resulting from joint efforts.

There must be regulations and rules to play by, however. Models for co-operation between academic institutions for the purpose of ODL is being tried out in several European projects, providing valuable experience as a basis for revision of models and for development of new ways for obtaining ODL to the optimal benefit for both students, staff and the institutions involved. Most valuable results and experiences have been acquired when both academic institutions and receiving organisations have been working together in the planning and development of ODL courses and material. Examples of such activities will be provided in the following sections.

Co-operation between academic institutions is launched as an educational policy, nationally as well as internationally, including the establishment of educational collaborative networks between centres of higher education and research. Several European countries state in their White papers or other political documents principles and guidelines for exchange and sharing of expertise between educational institutions. As an example of how positive relations between institutions and exchange of experience are stressed, the European Commission's Socrates programme has *partnership between educational institutions* as one of their criteria for allocating funds to R & D projects. These are stated in the EU guidelines for proposals under the Socrates programme, 1996 & '97 [1].

Enterprises throughout the world state that there is a huge need for updating of professionals. To meet this need we already see a growing tendency of real co-operation between enterprises and the formal educational system in order to train their employees. Normally the employer has responsibility for updating their staff, but by now we more often see a combination of updating the staff by offering them formal qualifications. Development of necessary curriculum to obtain formal qualification is based on co-operation or joint ventures between companies and the formal educational system. The companies play a central role in describing the needs and also are the ones to find or provide the professional know how.

Introduction of electronic networks, e.g. Internet increases the functionality and facilitates practical activities among co-operating institutions. Both academic staff, learners and the outside learning society are supposed to benefit from diverse specialisation and expertise, sharing of duties between institutions.

Together, the collaborating institutions may become able to provide a greater variety of studies to their learners than any one of the institutions can manage on its own. Collaboration should emphasise the importance of being able to utilise the various profiles, specialities and professional expertise of the different institutions and enterprises. This should increase both the width and depth of the learning environment.

One example of how institutional co-operation is demonstrated at a national level by the NITOL project (NITOL = Norway-net with IT for Open Learning). Four academic institutions in Norway have successfully practised their own model of co-operation since 1994. Much of the success in this pilot project is probably based on long-standing relations and trust between the key personnel involved. The project's primary goals were to :

- gain experience and develop methods for ICT based, open, flexible and distance learning at university level
- facilitate co-operative research and development between geographically separated academic personnel.

In order to approach these goals partners chose to:

- establish an open network making education within Norway-net available to students and other groups and individual participants from business, schools, administration, etc.;
- gain experience on distribution of educational materials through electronic networks;
- test the use of electronic conferences, mail, and WWW as the basis for group work and co-operative learning;
- develop an extensive, dynamic and creative electronic learning environment based on local and wide area electronic networks; now practically done on the Internet and WWW.

Organising NITOL

Despite the close relations and friendship between the active partner representatives in the project, a formal organisation had to be established in order to be prepared for disagreements or conflicts that might arise over economy, responsibility for students, networks, software, academic property etc. The signed contracts are mostly

BEST COPY AVAILABLE

dormant. In a few cases it has turned out very useful as reference and guidelines for disputes that arises. The project agreement is mainly in line with the project group's feeling of common sense, while the institutional contract is an important document when institutional authorities sometimes forget their commitments to NITOL.

Technical support and standards have proved to be important issues for ODL projects based on ICT. This always turns out to be a touchy issue between experts. Among the 'experts' in such a project there are tens of teachers and hundreds of students - who all have their own, well founded preferences for software and communication systems. On the other hand there are also many 'non-experts' or novices who need to be given simple solutions that fills their present needs. Among the latter group are also some of the course providers. It is therefore of outermost importance that the project group is able to make firm decisions, stick to the solutions given, and that there are able and committed people to support the technical system decided upon. As new technology develops and becomes available - outside the project - a careful balance must be found between existing, stable solutions and introduction of new, improved facilities for the project services. Responsibility for these technical decisions lies with the project group, while implementation and support is placed with one of the partners.

Objects of Collaborative Activities

Course Material

Together, the collaborating institutions are able to provide a greater variety of studies to their students than any one of them can provide on its own. The major advantage of collaboration is the exploitation of varied academic profiles and professional expertise, thus enhancing the curricula at both undergraduate and graduate levels, offering students and staff better professional environment. In addition, students may have a more flexible study programmes, working at the time and pace of their own choice, with few restrictions on attendance and location.

Because of the variety of professional profiles at the co-operating institutions, close collaboration strengthens the whole teaching and research environment at each institution. Through electronic communication it is possible to work together in a close and efficient manner in a "virtual" environment of co-operation. This has already been established between the NITOL institutions, and is spreading throughout the rest of the ODL environment. This is a system that effectively establishes and utilises contacts across the boundaries of institutions, regions and countries. Development of course material follows one of three different models for institutional cooperation:

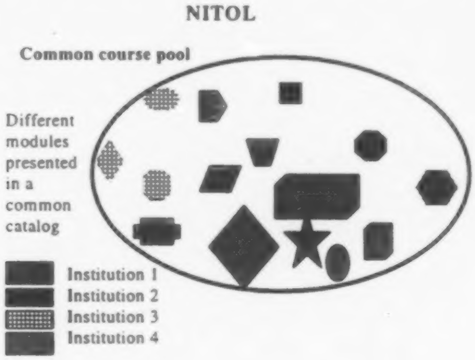

Figure 1: The open access model

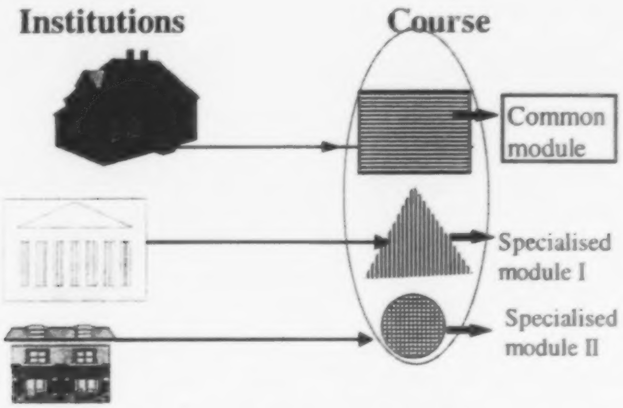
The Open Access Model (Fig. 1) is one of several models within the NITOL activity. This was the first one tested, where each institution offered some of their traditional courses, revised or redeveloped for electronic transmission to their own students as well as to outsiders. The model is also applied sin some of the European ODL projects.

The beneficiaries of this model are mainly the students, who have easier access and more choices of courses. The institutions and the professors gain experience in dealing with distant students and the colleagues' ways of presenting learning material - a golden opportunity to have a look at how colleagues present and design their teaching material, is a fringe benefit.

The Composite Model is practised when institutions compose larger courses by joining two or more modules developed at different institutions.



Institutions
Course
Common module
Specialised module I
Specialised module II

Figure 2: The composite model

The result could be a tailored study for special purposes or just an extension of a small course , which a single institution is not able to develop alone, due to restrictions on time, staff, expertise etc. This model seems to have value for colleges/institutions that are small or medium sized, where resources and the variety of the staff's expertise is limited. In the composite model, the institution responsible for the specific module, also takes full responsibility for the student activities within the actual module. Elaboration and marking of exercises are also a tried out as a collaborative, composite work, while assessment normally is done by one institution.

Joint Venture Model is a model where the main idea is continuos, real, close collaboration between the professors in joint development of course material. This means that two or more institutions within the network join forces in developing open, flexible learning material in the form of lessons.

Several EU based ODL projects are practising similar principles and methods to organise co-operation across institutional as well as international boundaries. Some of these projects worth mentioning in this context are under the Socrates programme [2], e.g.

A first evaluation of collaboration, assessing the intentions and the models described, identifies characteristics like *inspiration* both to students and professors, *improvement* in the quality as well as an *increase* in quantity of the courses offered. Partners involved through NITOL, MECPOL etc. seem to be satisfied and inspired to further efforts for open and flexible learning

Mutual Services

An important issue in the partnership agreement is the mutual recognition of credits, courses and modules between the partners involved. Students may thus choose modules and courses from a larger menu, combining it into more varied and specially tailored lines of study. It is, however, still up to the institution that issues the certificate to recognise the final combination of subjects and courses

External funding has played a central role in the early stages of NITOL and MECPOL. Applications and proposals for funding have turned out to be more positively viewed in cases where a collaborative organisation is already established. Project partners have in several cases entered as one body in the process of making proposals and application, and afterwards shared the benefits obtained through decisions by the project group.

Instead of competing for the same target groups with parallel courses in related fields, the project groups have consequently, from the start, issued common course catalogues for all the courses provided by the particular project partners. Even though the courses are provided by individual staff members at separate institutions, and marked this way in the catalogue, there are great advantages in joint marketing. Distribution of information becomes easier, potential students get a better overview, and large scale customers, like the Navy, can find a more varied offering within the same context.

After less than 3 years the NITOL concept already has more meaning to a lot people interested in ODL, than the name of each of the partner institutions. At the same time, each institution benefits from belonging to this group. the European project groups have not yet obtained the same status, but hope to do so over time.

Visions

The models for ODL through telecommunication, taking advantage of the institutional operation described above, may provide easier access and higher flexibility for all kinds of professionals to obtain in-service and further education, as well as taking new formal degrees, without leaving their regular work/duties or their families. With the growing familiarity of Internet, telecommunication and similar facilities in homes and at work places, the time may soon be ripe for higher education modules to be available *when* and *where* each learner finds a need or a desire for them. This will require policy changes affecting the success of *lifelong learning*, both at national and international levels.

Abstract: Although using HTML as a data exchange format in a client-server system is quite acceptable, and its platform independence has helped HTML to become the de facto standard today, use of HTML as a data storage format for WWW servers deserves examination so that a more useful model can be found.

In this paper we briefly describe a new data model, the HM Data Model, which offers far more advanced structuring capabilities than HTML. We believe that this more sophisticated model offers many advantages with respect to server management and user orientation.

We offer also a Formal method of mapping data structures based on HM-Data Model onto HTML documents.

1. Introduction

It is widely recognized that the Internet offers tremendous potential for education. For example, it is an excellent distribution channel for educational materials and courseware in particular. Normally, the term "dissemination of courseware over the Internet" refers to an interactive browsing of courseware using systems such as the World-Wide Web (WWW), the most well-known of the interactive information retrieval tools on the Internet.

HyperText Markup Language (HTML) is one of the main concepts upon which the World Wide Web is based. It provides certain capabilities: it provides facilities for describing how information should be displayed, it allows authors to include other forms of data in documents, (e.g. images, sound, pictures, etc.) and it lets them incorporate so-called computer-navigable links into documents. It is a markup language, meaning that it does not allow authors to specify exactly how the text will appear when it is rendered, but rather allows them to specify different basic elements of the text such as the level of heading. How the text is actually rendered depends on the machine it is being displayed on, and may appear different according to what fonts are available on that particular machine. To view WWW HTML documents, one of the many readily-available WWW browsers such as Netscape or Mosaic, which run on practically all hardware platforms, should be installed.

Normally, HTML is not just viewed by users using a client, but also is used to store documents on servers. Here, in contrast to the exchange of documents, it has a number of drawbacks.

Link anchors in HTML are embedded directly in documents, using so-called tags to mark the beginning and end of anchors. Using embedded links poses a number of problems in WWW documents. In particular, let us mention two the most well known problems related to the provision of courseware using WWW:

- First of all, references from one document to another are stored solely within the source document, making it impossible to follow links backwards or to find out what, if any, documents reference a given document. This leads us to the "dangling links" problem: often one must remove documents from WWW servers for one reason or another and the result often ends up being many links pointing to nowhere.
- Also, the lack of structure found in this simple data model is in need of much improvement. Thus, links in WWW are not context-dependent; all links in a document are present all the time. This has two major consequences.
    1. Firstly, the reuse of courseware materials is unsatisfactory, because an author can refer to other documents but cannot embed them locally with possibly new or different hyperlinks.
    2. Secondly, the presence of links completely unrelated to the current context (course) rapidly leads to reader disorientation.

The conclusion that can be drawn here is that although using HTML as a data exchange format in a client-server system is quite acceptable, and its platform independence has helped HTML to become the de facto standard today, use of HTML as a data storage format for WWW servers deserves examination so that a more useful model can be found.

In this paper we briefly describe a new data model, the HM Data Model, which offers far more advanced structuring capabilities than HTML. We believe that this more sophisticated model offers many advantages with respect to server management and user orientation.

We offer also a Formal method of mapping data structures based on HM-Data Model onto HTML documents.

2. The HM-Data Model

Current trends in logical data modeling can be classified into two main groups:

- Data models supporting links embedded within primitive nodes (i.e. links are local in the sense that they belong to individual documents);
- Data models supporting links as fully-fledged addressable objects (i.e. links are global in the sense that they belong to the hypermedia database as a whole).

In the HM-Data Model, information is not simply stored as HTML documents which have various references between them but rather is organized into units called structured collections (S-collections). An S-collection can be seen as a closed environment which contains a structure of navigable links between so-called Virtual Documents contained in it. Virtual Documents are documents which contain only information and not links. Virtual Documents contained in an S-Collection, are called members henceforth (see Fig. 1).

Thus, the HM-Data Model supports a third type of linking, conceptually somewhere in between the local and global link models. In the HM-Data Model, links neither belong to individual nodes (note that Virtual Documents are free of embedded links), nor they are globally addressable objects, but they are encapsulated within hypermedia containers called S-Collections. By definition, links cannot point outside an S-collection, but only between its members; hence S-collections represent well-defined chunks of information, which may be re-used in various contexts without concern for superfluous hyperlinks. The model compensates for the restriction of links to local contexts by introducing memberwise inclusion of hypermedia chunks and orthogonal browsing semantics to switch local context.

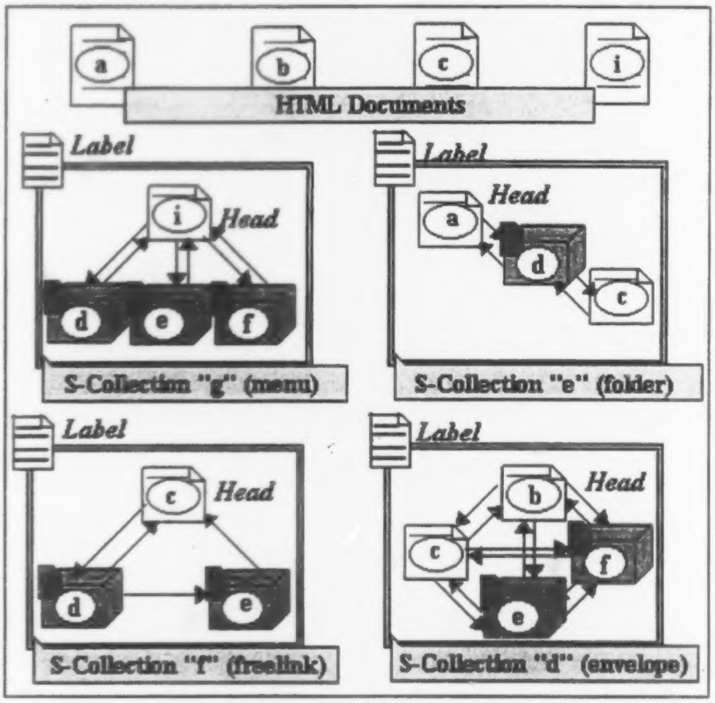

Figure 1: Internal Structure of S-collections

There are several predefined types of S-collection. An envelope has links back and forth between every combination of two members in the collection. A folder joins members into a list, with links to next and previous members. In a menu, one specific member (called the collection head) has links to and from each of the other members. Lastly, with freelinks, authors can link the collection's members in any manner they wish (see Fig. 1). Not only do menus have collection heads, but so does every other type of S-collection. The collection head is a member designated to be seen first when the user starts browsing an S-collection. This, as we shall see, is important with respect to the navigational mechanism in this paradigm. Also, an S-collection can have associated with it a label, a document which describes the content of that collection, and which is the first document seen when the user accesses the collection. These S- collections, which can be seen as separate containers in which only links between members of that container can be seen or followed, can also themselves be members of other S-collections and can have either other S-collections, Virtual Documents or both as members.

The nesting of S-collections can be arbitrarily deep. Recursive membership is possible, i.e. an S-collection can have itself as a member or contain another S-collection which has it as a member. Also, each collection is required to have a unique name which is used to support URL (Uniform Resource Locator) naming scheme. The name is used to access S-collections by means of WWW browsers and for specifying an S-collection for reuse (i.e. having the very same collection appear in two different S-collections and having it linked differently in each case). The reuse is possible as links are stored separately from virtual documents.

BEST COPY AVAILABLE

There are three important navigational operations, which are called OPEN, CLOSE and ACCESS. The OPEN operation lets users do just that- when they have navigated to a certain S-collection, have read its label and would like to explore its contents, they open it. As mentioned earlier, each S-collection has a certain internal structure. When one is opened, the environment the user is in is switched from one collection to another. The internal structure of the opened collection is there for the user to browse, so until another collection is opened, the user can only navigate within this collection, always starting with the head of that collection (see Fig. 2).

Current member
S-Collection"g"(Current container)
New current member
a
c
d
S-Collection"e"(New current container)

Figure 2: Operation "OPEN S-COLLECTION"

The CLOSE operation is the opposite of OPEN. It causes the user to leave the browsing environment of one collection and go back to the context of the collection in which it is contained. The third operation, ACCESS, is what the user uses to navigate between the members within a collection. It is similar to following a hyperlink, except that when users access a member of a collection, that member could be a virtual document or it could be another collection, and in this case, what they see first is its label, so they can decide whether to open it or access another member.

3. Projecting HM-Data Model onto the Web

As can be seen above, the HM-Data Model provides better structure and link maintenance than the data model currently used in the Web. If this model were used on Web servers it would save time and effort for server administrators and would also allow them to structure their data in a more advanced manner. It would eliminate the headache of link maintenance as this would be taken care of automatically. It would allow the same documents to contain different links in different contexts, allowing the reuse of information in various contexts. What we are suggesting is a union of the advantages offered by HTML and those of the HM-Data Model.

The idea is to use the advanced HM-Data Model to store information and to use HTML for that which it is well suited, i.e. the Mark Up and exchange of data. All that must be done here is to map the information and structure which is on the server onto elements that are well known in current Web terminology.

Virtual documents are prepared locally by means of an ordinary HTML editor and are stored into a special WWW server. Such virtual documents are further inserted into S-collections by means of a special authoring system running on the server site. S-collections can be accessed by a standard WWW client (for example, Mosaic, MS Explore or Netscape).

Thus, from users point of view, S-collections residing on the server can be treated exactly in the same way as conventional HTML documents. They are provided with URLs, and can be accessed and referred to from within other HTML documents. The only difference is that an S-collection encapsulates a particular navigational which is activated via an additional "Open" operation.

BEST COPY AVAILABLE

4. Formal mapping of HM-Data Model onto Node-Link model

The following notation is used hereby to refer to navigational operations available in the HM-Data Model:
1. (**<S-collection>**) Each S-collection is put into brackets symbolizing a closed navigational system of the S-collection;
2. → This symbol denotes the ACCESS operation in HM-Data Model
3. (→ This symbol denotes the OPEN operation in HM-Data Model
4. ↑) This symbol denotes the CLOSE operation in HM-Data Model

The following infer rules can be used by a software component (i.e. Gateway) converting a database structured in accordance with the HM-Data Model, into conventional HTML documents.
1. <Database> ::=<label>(<S-collection>)
2. <S-collection> ::=<folder>
3. <S-collection> ::=<menu>
4. <S-collection> ::=<envelope>
5. <folder> ::= <member$_1$><member$_2$>...<member$_n$>

6a. < member$_1$> ::=< member$_n$> | < member$_2$>

6b. < member$_2$> :: =< member$_1$> | < member$_3$>

6c. < member$_n$> ::=< member$_{n-1}$> | < member$_1$>

7. <menu> ::=<menu_head>
8. <menu_head> ::=<head><menu_member>
9. <menu_member> ::=<member><menu_head>
10. <envelope> ::=<envelope_member>
11. <envelope_member> ::=<member><envelope_member>
12. <head> ::=<label>(<S-collection>) | VirtualDocument
13. <member> ::=<label>(<S-collection>) | VirtualDocument
14. <label> ::=VirtualDocument

5. An Example

Let us consider the following user session. Suppose the user accesses the S-collection "g" (see Fig. 1) using a known URL. The label of the S- collection (i.e. the virtual document) is automatically converted to an actual HTML document by means of embedding additional navigational means (button "Open" in this particular case) , the resultant HTML document is displayed on a client site. Whenever the user "opens" the S-collection "g", head of the S-Collection "g" (i.e. document "i") is automatically converted to an actual HTML document by embedding menu of (i.e. links to) all the members. Suppose, the user activates the link to the member "e" which is in turn a complex collection. The S- collection "e" becomes the current member, and a virtual document defined as its label is displayed with a corresponding link to "I" and an additional anchor "Open". Now the user is able to "open" this S-collection "e". Once the S- collection is "opened" the head (i.e. document "a") enhanced with links encapsulated within the current container becomes available. Now the user may "close" the S-collections "e" and "g".

The sequence of operations generated by the above discussed rules may look as follows:

<Database>→<Label>(<S-collection>)

→VD-Label-g(<S-collection>)

→VD-Label-g(→<menu>)

→VD-Label-g(→<menu_head>)

→VD-Label-g(→<head><menu_member>)

→VD-Label-g(→VD-i<menu_member>)

→VD-Label-g(→VD-i→<member><menu_head>)

→VD-Label-g(→VD-i→VD-Label-e(<S-collection>)<menu_head>)

→VD-Label-g(→VD-i→VD-Label-e(→<folder>)<menu_head>)
→VD-Label-g(→VD-i→VD-Label-e(→<member_1><member_2>...<member_n>)<menu_head>)
→VD-Label-g(→VD-i→VD-Label-e(→Vd-a<member_2>...<member_n>)<menu_head>)
→VD-Label-g(→VD-i→VD-Label-e(→VD-a↑)<menu_head>)
→VD-Label-g(→VD-i→VD-Label-e(→VD-a↑)<head><menu_member>)
→VD-Label-g(→VD-i→VD-Label-e(→VD-a↑)VD-i<menu_member>)
→VD-Label-g(→VD-i→VD-Label-e(→VD-a↑)VD-i↑)

6. Conclusion

As can be seen, the data structure which is currently widely used in the Web is not nearly as advanced or useful as it could be. There are many well-known problems which are encountered when using HTML for storing data on servers. Still, HTML, with its platform independence, is excellent for the exchange of data between server and client. We believe that the HM-Data Model could provide and new and useful paradigm which would eliminate the problems caused by the fact that HTML documents have links embedded in them. Using each model for that for which it is best suited seems like an ideal solution to many of the problems of the Web today. This idea could be accomplished by mapping the rich structure of the HM data model onto the simple node-link paradigm found in HTML.

HM-Card, a software package that implements this model, as well as help files and a number of courseware examples are available from: http://www.iicm.edu/hmcard

Structuring Web Documents:
Are Multimedia Guidelines Useful to Web Designers?

Ise Henin
University of Victoria
P.O.Box 3045, Victoria, B.C., Canada
ise@uvic.ca

Abstract: This paper presents a report and discussion of a study completed by the author in May 1995 at the Faculty of Educational Technology at the University of Twente. Design guidelines for development of instructional multimedia documents were selected through a literature review. The guidelines were subsequently ranked by importance after testing their applicability on four commercial multimedia publications, including an analysis of the products' underlying design criteria. The five most important design tips for structuring multimedia documents were annotated in an interactive program for students of instructional design whose assignment was to develop programs using multimedia. The focus of this paper is to connect hypermedia research to the World Wide Web and uncover how many of the multimedia design guidelines pertaining to navigation are now standard features of web browsers; to identify which multimedia design criteria can be useful to Web designers; and to explore which guidelines for the development of good multimedia documents can assist in creating consistently-structured materials for the World Wide Web.

Introduction

Even though there are few design guidelines for structuring multimedia projects, complex compound documents that might include an interactive user interface, graphical images, hypertext, sound, animation and video are being developed, in great numbers, for a variety of display platforms.

With innumerable World Wide Web servers now containing hyper-linked materials, the question arises whether some of the guidelines developed for hypertext and multimedia documents can be useful to a "Web designer". On the Web, some of the features an author might wish to implement are incorporated in the browser software: by moving responsibility for document display from author to viewer, the author is left with less influence on a document's design.

This paper describes how a set of design guidelines for structuring multimedia documents was extracted from literature, reviewed in the context of commercial CD-ROM products, and used to develop an interactive program designed to help educational technology students structure their first multimedia documents. The discussion concentrates on how well, if at all, the guidelines useful to multimedia designers can help authors structure their materials for the Web.

Method and Procedure

The Literature Review

Eight recent articles [Horn (1993), Horton (1994a-c), van den Meiracker (1994), Rockley (1994), Smith, Munson, Lightner and Gregg (1994) and Webster (1994)] were reviewed for design guidelines useful to instructional designers embarking on development of multimedia projects. Five main design ideas were selected from each article and subsequently used as a 40-item checklist for evaluating the underlying design criteria of four published multimedia products. [Short reviews of all articles can be obtained from the author.]

The Product Review

Four commercial products, published on CD-ROM [Apple Computer (1994), MacWorld (1994), Maltwood Art Gallery (1994) and Norman (1994)] were scanned for compliance to the 40 guidelines described earlier. During the product review, screens that exemplify some of the 40 guidelines were saved, compared, ranked and used to select five of the most important design considerations found in current multimedia products that can be supported by recent literature. These five "tips" formed the foundation for an interactive learning aid developed for first-year students given the task to design multimedia documents.

Interactive Demonstration of Guidelines

A hypertext program "*Design Tips*" was subsequently developed (in Hypercard for the Apple Macintosh computer) to illustrate the design concepts in an interactive way: the program was designed to be used as both a model and a resource for a course on On-line Learning offered by the Faculty of Educational Technology at the University of Twente. The program's design incorporates 15 of the original 40 guidelines first identified in the literature, pertaining to navigation, content and visual design. The program was limited to five tips due to the time constraints of the project, but designed in a modular way for adding more guidelines at a later date.

Results

Five main design ideas from eight articles resulted in a 40-item checklist used to rank the five most important design criteria, supported by current research, that were applied in the four selected multimedia publications. A hypertext program incorporates the criteria in an interactive learning tool for students developing multimedia documents.

The Guidelines

The literature and product review yielded the following, most important design considerations:

1. To provide materials in small information units that are easy to navigate

Information should be presented in manageable, consistent information chunks in easy-to-read typeface and colours; with every screen displaying (in the same location, and in a similar colour and size) "Help" and "Quit" options, as well as "Forward" and "Backward" buttons for an alternative, linear path through the document.

2. To reveal the information in increasing levels of detail

It is better to allow the viewer to select more detail than to present more information than necessary on one screen: use of inserts and expanded views in any form such as tables, photographs, animation, and graphics can add the necessary level of detail on demand.

3. To focus on substance and avoid inundating the viewer

Technology should not overwhelm the substance of the presentation, and art and design criteria should be subordinated to the objective. Overloading screens with uninformative lines, boxes, decoration, or colour is confusing: superfluous detail should therefore be avoided.

4. To provide an overview of the contents

An interactive list of contents should be designed with each level leading to a lower level providing more detail. References to numbered screens (which are analogous to page numbers in a print-based document) are not necessary in an interactive list of contents since selecting a topic will display the pertinent information. For small projects it is sufficient to design a screen that clearly lists the main points the program can access.

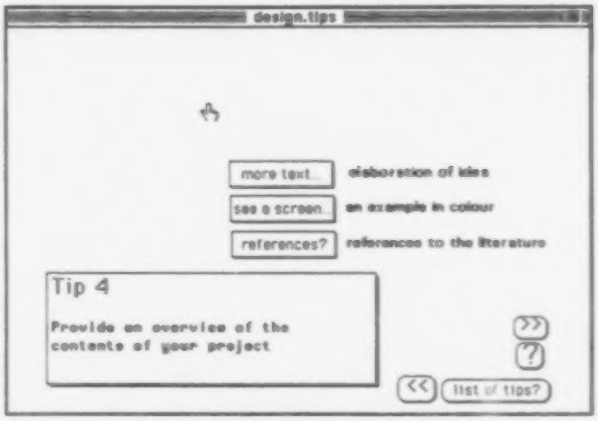
5. To index the information

When the program is complex, an index seems indispensable. To be able to access the information by keywords and by screen number helps those users who know what part of a program they wish to access and who might resent having to work through layers of screens, menus or information windows to get there.

The Interactive Program to Demonstrate Guidelines

The hypertext program "*Design Tips*", in addition to incorporating 15 of the original 40 guidelines to illustrate 5 design criteria, presents a total of 24 screens of information on a grey-scale image background; provides 17 buttons which access 155 navigational links (of which 61 are generic and 94 are contextual); and provides buttons that display 84 associated fields of text and 5 graphic colour images. Two screens of "tip 4", *explanation* and *elaboration*, can be seen in Figures 1 and 2 below (the background design is omitted).

Figure 1

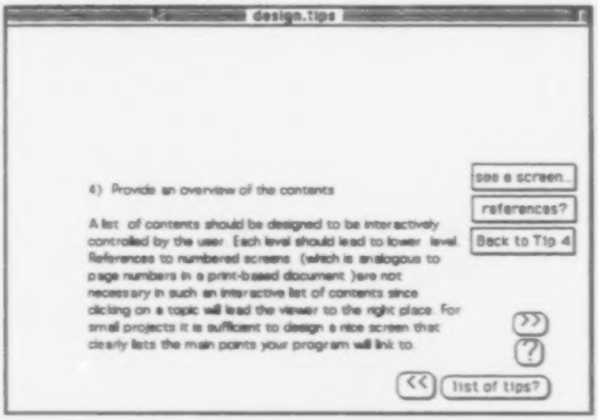


Tip 4

Provide an overview of the contents of your project

Figure 1: Tip 4 Explanation

Figure 2



4) Provide an overview of the contents

A list of contents should be designed to be interactively controlled by the user. Each level should lead to lower level. References to numbered screens (which is analogous to page numbers in a print-based document)are not necessary in such an interactive list of contents since clicking on a topic will lead the viewer to the right place. For small projects it is sufficent to design a nice screen that clearly lists the main points your program will link to.

Figure 2: Tip 4 Elaboration

Contextual Navigational Links

The program displays each of the top five design tips as a small unit of information. Hypertext links can be made to three levels of depth: (a) for elaboration—to view explanatory text, (b) for an example—to view a screen captured from a reviewed multimedia product, and (c) for further study—to view reference materials. These links are contextual links, based on the information content.

The contextual buttons are always placed in the centre horizontal band of the screen and are represented by square rectangles. In addition, main menu choices are also centred in the vertical band of the screen, while other choices appear on the right hand side above the generic buttons (described below) to reduce unnecessary mouse movements.All contextual buttons have associated fields of text, while the "example" buttons have associated graphic images. All fields have been locked individually to prevent changes and are displayed in consistent fonts, font sizes and attributes.

BEST COPY AVAILABLE

Generic Navigational Links

In addition to the contextual links, generic navigational links are provided: a "Forward" button provides a linear path through the information while a "Rewind" button presents the information in the order accessed by the user (on a last-in, first-out basis). The generic buttons appear on every screen provided they are appropriate (no "Forward" button is placed on the last screen, for example). These buttons are oval rectangles and always appear in the same position in the lower right hand side of the screen.

A "Help" button provides on-line help (which returns to the section where help was called from, upon activation of a "Done" button). A "List of Tips" button returns to the main menu screen. A "Stop" button ends the program when called from the main menu, an "End" button terminates the program when the last screen (credits) is reached. In addition, a "Start" button has been built in, its sole purpose being to provide a link that can connect future additions of new modules.

Discussion

How pertinent are the above design guidelines to the Web since they were devised for multimedia publications, which are self-contained and can be controlled by the authors? Web documents, on the other hand, might be stored on a variety of servers, are accessible from multiple sites, with document display controlled by the viewers or the settings of their access software (the browsers) rather than controlled by authors.

Options now Handled by Web Browsers

Some of the multimedia design guidelines pertaining to navigation are now standard features of web browsers: The user can determine what typeface and colours are easy-to-read; every screen displays, on the toolbar and in the same location, a "Stop" option, "Forward" and "Back" buttons, as well as an option of returning to the "home page" (the initial screen analogous to the main menu). The standard buttons, however, neither provide on-line help nor a linear path through the document, a feature anyone who has tried to print a complete, long Web document would have appreciated.

Criteria Applicable to Web Documents

A still applicable, and most important, design guideline for structuring Web materials is the requirement that information be presented in small information units: the method of Structured Writing described by Horn, (1993) which was developed 25 years ago, can still act as a guide for providing the, often missing, structure and consistency for a Web document. Information blocks, identified by a descriptive label, replace traditional paragraphs as logical units describing core parts of a limited topic. Each block forms part of a larger structure which collects all items related to a specific topic. Classification of contents and formulation of precise labels help the author to clarify the concept and the reader to anticipate, scan and find the information.

Another important guideline, since it saves band-width as well as reducing time users might need to wait for, possibly irrelevant, information, is the rule to reveal the contents in increasing levels of detail: opening a link in an ordered list, for example, can provide an expanded view of an item in context; clicking on an image map can provide detailed illustrations; providing thumb-nail graphic images in low resolution can help the viewer determine if down-loading the full picture is appropriate.

A guideline that appears to be unnecessary since viewers (instead of authors) control the screen display, must, nevertheless, be mentioned again: the need not to clutter valuable screen space with superfluous detail such as background textures, illegible text colours, excessively-complex tables and moving text or images: such tactics are often apparent at commercial sites. While it is pretty easy to avoid clutter by turning off the display of graphic images or using a text-only browser, by site designers following this guideline they might regain viewers who, disturbed by overload, tend to avoid a cluttered site.

Since building an index for full-text retrieval can be tedious in multimedia documents, especially when components such as video clips have to be linked in manually, see Rockley (1994), index building is only advisable for complex programs. On the other hand, making a Web document searchable requires only one HTML command which should therefore never be omitted.

Ideas Suitable if Modified for the Web

The multimedia design guideline to generate a "table of contents" which can be accessed interactively is easily incorporated into Web documents. By displaying links in one of the HTML list structures (such as menu, ordered, standard, unordered or definition lists) and by assigning meaningful labels to the items in the list, list structures can act as implicit tables of contents.

The suggestion to reference screens by numbers, on the other hand, is illogical in a Web setting, since screens are not of a fixed size but contain varying levels of information depending on the preferences set in the browser. This idea has been carried over from books and a better method and analogy must be found to visualize where a screen of information is positioned in the context of a complete document.

Further Research

Designing for the World Wide Web presently still appears to be more of an individual (and cumbersome) rather than a collaborative task, difficulties in finding a common ground for collaboration are more likely to be overcome if more research becomes available on what "works" and what does not, especially if the software developers apply this knowledge to develop better and easier-to-use tools. Evaluation of user preferences; of content accessibility; of browsing and authoring tools, and their user interface; and research linking hypermedia knowledge to emerging web standards are areas where much work remains to be done.

Conclusion

This paper has briefly considered how design guidelines found in literature for multimedia projects can be applied by educational designers presenting materials on the World Wide Web. The concern with design aspects of the Web are important due to the necessity of having to organize massive information of varying types, and across locations; the difficulty of the task of displaying the information on (rather limiting) flat screens; and the requirement of having to provide links to the information spaces in a logical, easily visualised, and consistent manner.

On the Web, addressing the need to provide tools for search, visualisation and display of the information is in the software developers' domain; addressing the need to provide contents and structure is in the authors' domain: neither can succeed if those seeking out Web documents cannot find the information, consider it useless, or consider the access tools unusable. To work collectively on identifying and resolving usability issues continues to be critical.

Abstract: Workplace learning provides a rich environment for investigation of the *learning web* approach since it involves learners with well-defined job roles collaborating in goal-directed activities. There are not only general learning needs in order to fulfill the roles but also highly focused 'just in time' knowledge and skill requirements. This article reports on an initial experiment to integrate the workplace learning environment with the ongoing workplace activities in such a way that the support of learning is an integral part of the organization's primary activities. It focuses on providing a group communication and negotiation environment in which the specialist roles of the individuals involved are modeled within the system and are explicit in the interactions and services involved.

1 Introduction

The learning web has been introduced as a model for collaborative learning through self-organizing communities operating through distributed networks that transcend conventional institutional, regional and national boundaries (Norrie and Gaines, 1995; Gaines, Norrie and Shaw, 1996), and examples have been given of its implementation for undergraduate education (Shaw and Gaines, 1996). However, the transformation expected in adult education through the learning web approach can best be illustrated through learning environments that are not confined to existing educational institutions but address issues of lifelong learning through the support of individuals and groups operating in the workplace.

The workplace learning environment differs from that of the university because those involved have well-defined functional job roles supporting the objectives of the organization of which they are part. Their learning needs arise out of the adaptive processes entailed by their roles, and are often highly focused on particular 'just in time' knowledge and skill requirements. There are also longer term, transformatory learning requirements as roles and job requirements change that can be satisfied by conventional education and training courses, but the workplace environment has a major emphasis on learning linked to immediate needs and to the support of goal-directed group processes.

The learning web models addresses these more diverse requirements of workplace learning through a unified model that recognizes *communities of knowledge* (Shaw, 1985) and adopts a *collective stance* (Gaines, 1994) which treats organizations and teams as learning individuals similar to individual people. The learning needs of work groups and individuals are modeled as resulting from the recursive sub-division of the organization into partitions similar to the organization as a whole—a model similar to Warnecke's (1993) *fractal company*.

Thus, we do not see the support of workplace learning as being primarily a problem of 'distance delivery' of conventional adult education courses, although that can certainly play a significant role. The significant requirement that differentiates workplace and university education is to integrate the workplace learning environment with the ongoing workplace activities in such a way that the support of learning is an integral part of the organization's primary activities. This article reports on an initial experiment to achieve such seamless integration using the learning web approach. It focuses on providing a group communication and negotiation environment in which the specialist roles of the individuals involved are modeled within the system and are explicit in the interactions and services involved.

2 Requirements Negotiation as an Example of a Generic Workplace Activity

The task chosen as providing a reasonably generic instance of a common organizational function was that of negotiating system requirements between various 'problem owners' and 'system developers' within the framework of Checkland's (1981) *soft systems methodology*. This situation is a common one in all organizations and usually involves learning on the part of both the system specifiers and the suppliers as both groups adapt to one another's needs and capabilities in a dynamic environment. There are two major approaches to what has come to be called *requirements engineering*, that of *participatory design* (Schuler and Namioka, 1993) and that of *joint application design* (August, 1991), and the system supports both approaches.

The general roles defined for the requirements negotiation task are:

- the *facilitator*, who acts as a chairperson of the meeting
- the *users*, who are people involved in using the system, are the "owners" of the problem.
- the *analyst*, who transfers the requirements from the "problem owners" to the design team.
- the *design team*, who are the system implementors, are responsible to meet the elicited requirements.

Other examples of the learning web in action (Shaw and Gaines, 1996) have used the standard facilities of the World Wide Web, sometimes supplemented with constructivist modeling tools operating through the web (Shaw and Gaines, 1995). For the workplace studies we needed tools that explicitly supported structured collaboration in a way that was not yet available on the web, and chose to use the TeamRooms system (Roseman and Greenberg, 1996) which is implemented as an Internet or intranet application using the groupware toolkit GroupKit (Roseman and Greenberg, 1992).

TeamRooms combines shared whiteboards, chat rooms and other customizable groupware applets (integrated mini-applications) in a persistent work environment that lets participants easily and flexibly collaborate and share information with colleagues across a network. The model for TeamRooms comes from real-life team meeting rooms, which provide a shared space for a workgroup. TeamRooms works the same way, except that the room and its objects are now a fully graphical, persistent groupware interface.

3 TeamRooms as a Negotiation Place for Requirements

The first step in customizing TeamRooms to support a learning web concerned with requirements negotiation was to analyze the roles of the major participants using Checkland's soft systems methodology as shown in the concept map in Figure 1.

Figure 2. The layout of rooms in the iterative cycle of requirements negotiation

The requirements negotiation process is about navigating this electronic workspace. The participants enter any of these rooms by clicking on the "door" of any room.

4 Collaboration in the Electronic Workspace

Awareness of other users in the work space is very important in simulating the real physical space. The list of users currently connected to the group's server, as well as the room each user is currently working in facilitates locating the other users and making contact with them.

The facilitator, who acts as a chairperson of the meeting, has a critical role in organizing the work of the requirements negotiation team. She enables effective communication, works as a project manager for the elicitation team, can have the knowledge of the room and action of each participant in the working space. She can use the **Work Agenda** Room to organize the work through an agenda of the meetings and lists of activities, using the Outliner or the Note Organizer applets to create a hierarchical activity structure, or a Concept Map applet to identify and set priorities.

Figure 3 illustrates the **Future Consideration** Room, a "storage and future retrieval" area. Exploring the users' environment, the capture team collectively investigates the target users' organizational setting and identifies and describes what they do. They produce documents recording the shared view of the users' environment. They create objects reflecting the users' workspace and save them in a database. Records in this database are files containing information that describes these specific objects. Users of the system may retrieve these files using the File Holder tool. Any file editor would give the participants the opportunity to read and modify the content of the files, after they discussed the changes with the others in the room.

The **Documentation** Room may be used by the analyst to record the elicited requirements. Documenting the elicitation process may be a time consuming task in usual physical meetings. Using the **Documentation** Room in the electronic space, the analyst records all information that participants generated, all the analysis conducted, all of the decisions reached, in hypertext format, creating the requirements documents. This way the documentation files have a higher quality, they are easier and more quickly produced. Validating

reveal moving pageant of relationships, and pictures are a better means for recording relationships and connections than in linear prose (Checkland and Scholes 1990). The example used in describing the content of these rooms is from a requirements negotiation process for a library system.

As a next step, an initial list of requirements may be proposed and stored in a generic "wish list", in the **"Wish List"** Room. The list of contents for a set of issues related to the requirements document is stored using the Outliner tool that helps in analyzing the information. It enables users to build upon a previously generated list and refine it into a hierarchical structure. In their "discussion" participants are helped by telepointers. They can see the other's cursor location on the document. In face to face meetings, hand gestures play an important role to communicate ideas. Telepointers are examples of a fine-grained awareness of others' actions in the workspace.

Figure 5 illustrates the screendump of a lending transaction prototype. The image tool has been used to retrieve it. Participants in the process use it in checking the accuracy of the elicited requirements; they use a Web browser to retrieve the requirements documents.

5 Conclusions

The system described is an initial experiment in using the learning web approach to provide a system that integrates the workplace learning environment with the ongoing workplace activities in such a way that the support of learning is an integral part of an organization's primary activities. TeamRooms provides the facilities to make available a wide range of resources in a structured environment that recognizes and supports the specific job roles of the participants. Some of these resources will be the products of the ongoing activity. Others will provide access to knowledge that supports the 'just in time' learning necessary to carry out the

BEST COPY AVAILABLE

activity effectively—these will look like 'information retrieval' facilities. Other resources will provide access to background materials necessary to operate more effectively in the roles—these will look like 'education and training' facilities. However, from a user perspective these differences will not be particularly significant because they will see the entire system as supporting their ongoing activities in a seamlessly integrated fashion.

The requirements negotiation process was chosen because it is of particular interest to our industrial sponsors and it is also a reasonably generic activity that occurs in most organizations. However, support of workplace learning can be integrated with virtually all activities that can be supported by a computer-based system. As 'workflow' support systems (White and Fischer, 1994) come to be common in industry they will also come to serve as vehicles for the delivery of workplace learning. As many learning needs are common across many industries, we may expect to see the *electronic data interchange* (EDI) paradigm extended to one of *electronic learning exchange* (ELE) in which the specialist training materials of one organization are provided to others to facilitate collaboration or as a revenue source.

Specification and Implementation of an Adaptable Virtual Class

Arturo Hernández-Domínguez
Departamento de Sistemas e Computação (DSC)
Universidade Federal de Paraíba II
Campina Grande/Paraíba, Brasil
e-mail: arturo@dsc.ufpb.br

Abstract. This paper describes a virtual class which is based on the principles of CSCW (Computer Supported Cooperative Work) and ICAL (Intelligent Computer Aided Learning) systems. The virtual class proposed allows to a group of learners to participate in training sessions of an adapted tele-teaching system or adapted virtual class, this system takes into account progression rhythm differents inside a community of remote learners. The virtual class allows to adapt the teaching system in a flexible, individual, and collective way. This system allows also the implementation of a pedagogical method: the cooperative learning. This implementation is developed in a distance education context using a telematic network. An application of this system in a multi-site environment of teaching of the accounting domain is described. The development of this system has been realized as a distributed application, the system of development used is the RPC (Remote Procedure Calling) product and the C and C++ languages.

I Introduction

The principle of the architecture proposed for an adapted training service is to allow the adaptation of knowledge transmission from a teaching function managing a virtual group of learners by a communication system (figure 1). Teaching functionalities are distributed taking into account the participation of teachers, system, resources and learners in some cases (when a learner has the knowledge or experience necessary for playing the teacher's role).

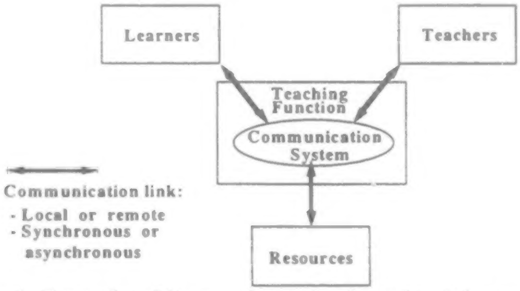

Figure 1: General architecture for each adapted training service.

The majority of learning telematic systems developed do not or rarely enable the system to control the teaching module. In general this function is controlled by the teachers, in the same way as traditional classrooms. In this paper, we propose for each adapted training service that the system allows to distribute the teaching functionality with the participation of teachers, learners and resources in a virtual class system.

II General Architecture

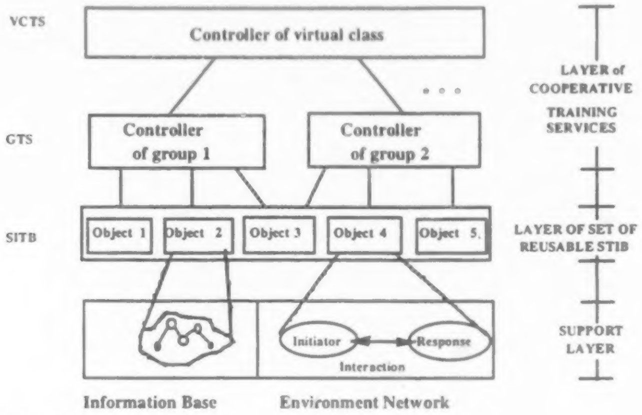
In the multi-site environment of tele-teaching, we propose that any training site must be represented according to the ARESFED (In french: "Architecture pour la Reutilisation et l'Exploitation des Services de Formation dans le contexte de l'Education à Distance") [Hernández 95d]. This architecture is composed of three layers: support layer, layer of a set of reusable SITB (Service Independent Training Building Block) and a cooperative services layer [Hernández 94c], [Hernández 95c], [Hernández 95d] (figure 2).
In this way, the representation of each training site is simplified and standardized. Thus, we must specify only an architecture: the ARESFED.

II.1 Support Layer

It represents a set of frameworks from which the training architecture is built:

BEST COPY AVAILABLE

Information Space, provides information management services relevant to the courseware developed (for example: an object-oriented database management system stocks all the reusable objects).



SITB: Service Independent Training Building Block
GTS: Group Training Service
VCTS: Virtual Class Training Service

Figure 2: Training architecture of a virtual class.

Communication Space, supplies services supporting a distributed system and network services.

II.2 Layer of a Set of Reusable SITB

This layer is represented by a set of functional, independent, and reusable components. These components will be shared and reused for creating a new service. We have identified with a participation of educationalists two kinds of resources: didactic (teaching activities) and information resources ("bricks of domain")[Canut 94], [Vincent 94].

From reusing of these types of resources a training service can be specified as a dynamic training service. The criteria of reusing of didactic and information resources are determined by learner's educational needs. The dynamic training service must diagnose an adequate resource that responds to learner's educational needs. In this way a dynamic training service is considered as an adaptable service.

II.3 Cooperative Service Layer

This abstraction level represents the two kind of cooperative training services provided by this architecture. We consider two kind of adaptable services [Hernández 95c]:

a) global level represents a virtual class composed of a set of remote learner groups and
b) local level represents a particular learner group, each remote learner group is classified by a knowledge level.

These two classes of cooperative services must be adaptables to learner's behavior in a training session.

The composition criterion of virtual class takes into account a pedagogical context, this pedagogical context is based on the cooperative learning [Doyon 91]. A virtual class will be composed of a set of heterogeneous groups, each group allows to a set of remote learners to participate to a training session. In a traditional class the homogeneity of knowledge level is not always assured. Some cases, this homogeneity of knowledge level becomes very superficial. For solving this problem, we consider a first level of adaptation to learner's educational needs, this first level correspond to take into account a composition of a virtual class from heterogeneous groups. These groups have a variable composition [Hernández 95d]. Each heterogeneous group corresponds to a different level of knowledge allowing to characterize a group of learners with the same level of knowledge about a particular domain. However, inside a group of learners is possible to find different behaviors of learners according to progression rhythm of each learner. The second level of adaptation is taken into account into a group of learners. A particular knowledge level associated to a group of learners may also become superficial and not adapted. For preventing this problem, we propose to consider the behavior zones into a group of learners. In this case, it is necessary to allow and manage the change of behavior zone of a learner inside a group (*inter-group change*) for assuring an adapted knowledge level of learners inside a particular group (local view). For assuring an adapted virtual class (global view) is also necessary to allow and manage the change of group (*intra-group change*).

II.3.1 The Adapted Training Service of a Virtual Class

The adapted training service of a virtual class has as principal functionalities:

a) the managing of progression of a set of remote learners,
b) the controller of the VCTS (Virtual Class Training Service) takes into account a pedagogical, structural and adaptable control of a virtual class.

An initial composition allows to create a set of heterogeneous groups, this initial composition is based on a learner evaluation. However, for preventing that the initial distribution becomes static and not adapted during a training session, we must consider a *logical mobility of learners*. This logical mobility must respond to learner's educational needs according to behaviors detected of a group of learners during a training session. So, two levels of distribution of learners have been considered: *variable groups* corresponding to level of class and inside a group of learners, that is a set of *behavior zones* have been established (figure 3) [Hernández 95c].

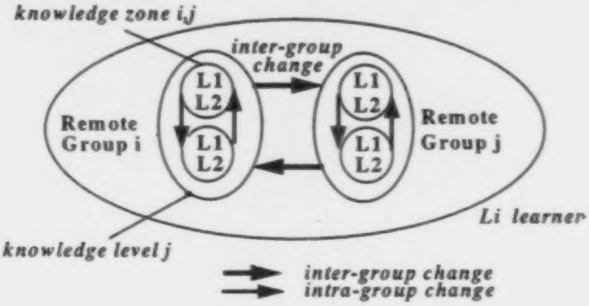


Figure 3: The distribution of learners in the virtual class.

II.3.2 Group Training Service

A controller of a Group Training Service (GTS) must adapt a training session to learner's educational needs.
The actors considered in a virtual class are: remote learners, teacher and shared didactic resources (didactic and domain entities).
A didactic interaction is a teaching interaction of cooperative type based on the roles played by actors. A role may be played by several actors [Depaoli 91].
A local didactic strategy is represented by activating didactic interaction. These didactic interactions are managed by the controller of a GTS.
The controller of an GTS must establish a dialogue with the controller of the virtual class. This dialogue allows to indicate either a learner may change of group or a learner has a problem or a learner send a request (when he wants to express a problem or point of view).
We established with educationalist team three behavior zones inside a group, these behavior zones represent three types of possible progressions: normal, intermediate and critical zones [Hernández 95c]. The control of these behavior zones represent a *fine adaptation to knowledge level* and to learner's educational needs.
The architecture for each controller of a group training service (GTS) was specified in [Hernández 95d].

III Specification of the VCTS

The VCTS must assure the knowledge transmission of a domain to teach. The VCTS has to manage a training session of a virtual class which is composed of a set of remote learner groups. It must also supervise and adapt the execution of a pedagogical strategy in a flexible way.

III.1 Architecture of Controller of the VCTS

The controller of the VCTS is composed of the following modules [Hernández 95d] (figure 4):

a) managing module of communication (event manager) with each controller of a GTS. This module must analyze each event sent by a controller of a GTS.

BEST COPY AVAILABLE

b) pedagogical module must manage a pedagogical strategy. The principal objectives of this module are: managing of pedagogical goals (knowledge transmission and knowledge evaluating), supervising of homogeneity of knowledge level associated to each group, and providing pedagogical aiding. This pedagogical aidings may be provided by different ways: using a didactic resource which is represented by a computer intervention, a teacher intervention is necessary for having similar functions as a traditional class (explanations, resolving doubts, providing advises, ...), and in the context of cooperative learning a learner intervention is also necessary.

c) behavior managing module of a group of learners. The VCTS has a *global view* of a virtual class composed of a *set of groups*. The global view is represented by a *set of group profiles*. Each GTS has a *local view* which is represented by a *set of learner profiles*.

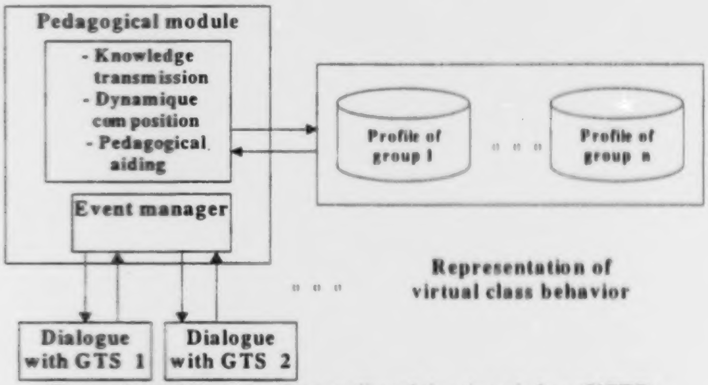

Figure 4: Architecture of controller of the virtual class (VCTS).

Now, we are going to develop the architecture of the VCTS.

III.2 Managing Module of Communication

This module is represented as a module that manages all interaction with each controller of a GTS. These interactions between controllers are represented by events. An event is considered as *a client-server interaction* between controllers. The controller of VCTS must manage each event sent by a controller of GTS. The event is analyzed and an interaction must be established. The controller of VCTS gives a response by an event. This event may be an *pedagogical goal*, a *change of group*, and *get in contact with a teacher or another learner*.
All dialogue event between controllers is represented by a pedagogical control interaction according to an object-oriented approach [Hernández 95c]. The execution of an interaction correspond to execute a communication protocol [Hernández 95d].

III.3 Pedagogical Module

The ICAL system must adapt a pedagogical method according to learner's educational needs [Canut 90].

Training session

A course is represented by a set of training sessions which are composed of general pedagogical objectives. A progression class is managed step by step: a general pedagogical objective is represented by a set of intermediate pedagogical objectives. Each intermediate pedagogical objective is associated to control interactions ("speak", "inform","tutor", and "ask-answer").

ADAS process

The VCTS controller works according to *Action-Decision-Analyze-Supervision (ADAS) process*, this process is also used for specifying the didactic module of a GTS controller. The general way of ADAS process is represented by the following representation.

Supervision *------- When an event is detected*
Analyze *------------------ Analyze type and context of an event*
Decision *---------------------- Diagnose roles and actors*
Action *------------------------------Establish to pedagogical control interaction and*
Execution of pedagogical control interaction

An event receipt may be: a status of a pedagogical objective (*status-pedagogical-objective*), an important regression (*regression*) or an important progression (*progression*) of a learner.

Pedagogical objective

The transmission of a pedagogical objective is represented by a pedagogical control interaction (figure 5).

Type of interaction: "pedagogical objective"
Parameters: "next pedagogical objective"
Type of relation: "1..1"
Context of interaction
Scope: string
Actor_initiator: "id_GTS"
Role_i: "client"
Actor_answer: "controller of VCTS"
Role_a: "server"

Figure 5: Representation of the pedagogical control interaction: next pedagogical objective.

```
When status-pedagogical-objective is OK
        next pedagogical objective = pedagogical strategy
                                        (current pedagogical objective)
        instantiation of next pedagogical control interaction
        execution of next pedagogical control interaction
```

Dynamic composition and pedagogical aiding are also represented and analyzed as a pedagogical objective, that is, a pedagogical control interaction and a ADAS process are also established and executed [Hernández 95d].

IV An Implementation of an Adapted Virtual Class

An example of a virtual class in the context of SEMIEC (In french: Service Evolutif Multimédia de Enseignement de la Comptabilité) has been developed at IPST (French institute for professional training) [Hernández 93b]. The tool of development was the product RPC (Remote Procedure Calling developed by Sun Microsystems) [Bloomer 92] allows to develop distributed systems. The architecture used is based on reusing of reusable SITBs. The pedagogical control is distributed between: the controller of virtual class (VCTS), the manager of SITB server, and the controller of group of learners (GTS).
Several RPC servers have been developed allowing to manage the events (figure 6). We have specified a server associated to each learner, a server is associated to the teacher, a server is also associated to controller of VCTS for managing the communication with a controller of an GTS, and a server of reusable SITB is implemented to manage the reusing interactions.
This architecture allows a distributed processing of pedagogical control. The programming of this application has been realized using of the language C for managing the communication channels and the language C++ for implementing the cooperative interactions according to an object-oriented approach.

V Conclusion

The architecture of the virtual class proposed is a response to traditional virtual classes which are not adapted. The virtual class proposed takes into account different types of learner progressions (behaviors). The virtual class considered is adapted allowing and controlling the learner mobility. This logical mobility may be inside a learner group (intra-group or change of zone) and outside a learner group (inter-group or change of group). This system provides a teaching function distributed between different actors: learners, teacher and resources. This teaching function allows: to use of cooperative learning, to give remote pedagogical aidings, and to apply remote tutor functions.

Works are in progress for implementing a server of reusable SITB in the object-oriented programming methodology domain. This server will be implemented using of Internet, the access to server will be analogous to a learning environment. The same server will be also used for reusing a set of reusable SITBs and adapting them in a virtual class by Internet.

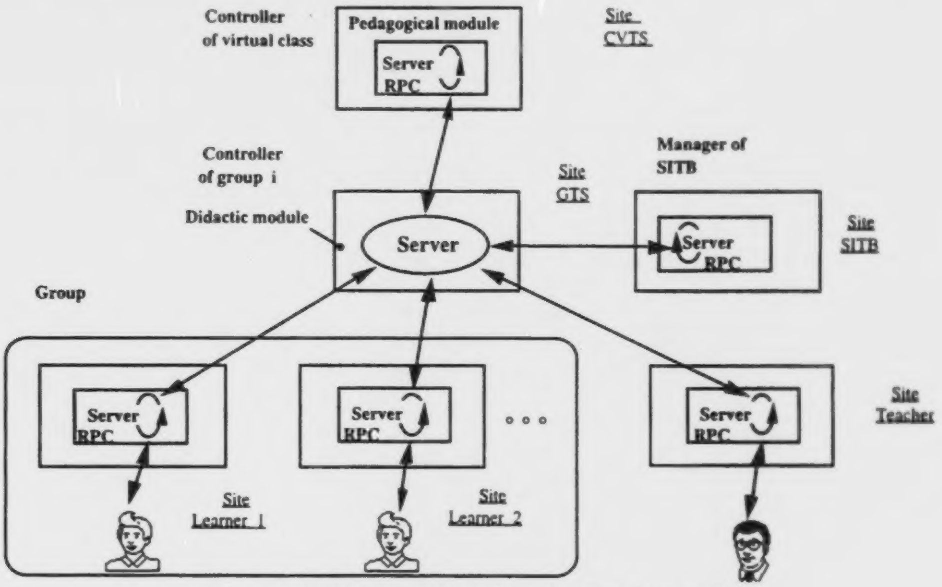

Figure 6: Architecture of an adapted virtual class on RPC.

Abstract

Many interactive multimedia programs direct learners down a one-way street. This paper describes a program based on a situated learning model which sought to open up the 'avenues to understanding'. Nine critical characteristics were defined from the extensive literature on the situated learning and used to inform the instructional design of a program on assessment strategies in mathematics. The paper describes a preliminary evaluation of the situated learning framework by investigating the use of the multimedia program by two students, and their thoughts opinions and feelings about learning from this type of program. Early findings indicate that it is a successful approach enabling students to construct their knowledge about the topic in an effective, non-linear, and collaborative manner.

Introduction

There has been much use of the travel metaphor in the educational technology community in recent times. There is talk of the superhighway, the fast lane, traffic congestion, and express delivery. And yet much of the interactive multimedia available today is more akin to a single, one-way street than a superhighway. In the one-way lane, there are few options once you begin. There are no feeder roads, no exits, no turns, no signposts, no choices. The student using such a program is a captive audience who must proceed from beginning to end, responding in a manner deemed appropriate by the designers, interacting with the program in foreseen ways, and exiting at the end without contributing to the lonely, sober journey.

This paper describes a program which was designed to put the student back in the driver's seat with a map, a destination and co-drivers. It enables learners to leave the one-way lane and investigate whichever avenues or highways they choose. The program began with a different theoretical framework. The prevailing model for the design of multimedia programs at the time of commencement was comprised of several steps, typically: a question or problem of some sort is displayed; the student is required to respond actively, for example, by selecting an answer; feedback is given, such as praise for a correct answer or correction of an error; errors are minimised by presenting material in small steps or by using techniques such as prompting and chaining; and students are free to work at their own pace. This model has been used to guide much of the multimedia developed to date. It is the format used by Skinner in the 1950s for the programmed instruction used with early teaching machines (Farnham-Diggory, 1992), but is still recognisable in many contemporary multimedia programs. It is understandable that Brown (1994) has asked for recent learning theory to be used in preference to 'outmoded theories of learning that are relics of psychology's behaviouristic past'(p. 11). Other authors and developers, such as Park and Hannafin (1993), and Lebow (1993) believe that little more than technological capacity and the intuition of designers are driving the design of multimedia, rather than research and theory.

The theoretical framework used to guide the development of this program was that of situated learning (Brown, Collins, & Duguid, 1989; Collins, Brown, & Newman, 1989; Lave & Wenger, 1991; McLellan, 1993; Young, 1993). Nine critical characteristics were defined from the extensive literature on the subject and used to inform the instructional design of the program. The learning environment needed to:

- provide an authentic context that reflects the way the knowledge will be used in real-life;

- provide authentic activities;
- provide access to expert performances and the modelling of processes;
- provide multiple roles and perspectives;
- support collaborative construction of knowledge;
- provide coaching and scaffolding at critical times;
- promote reflection to enable abstractions to be formed;
- promote articulation to enable tacit knowledge to be made explicit; and
- provide for integrated assessment of learning. (Herrington & Oliver, 1995, p. 255).

A program was developed to enable teachers and pre-service teachers of mathematics to explore issues of assessment, entitled *Investigating Assessment Strategies in Mathematics Classrooms* (Herrington, Sparrow, Herrington & Oliver, 1996). Twenty three assessment strategies suitable for use in K-12 classrooms were identified and presented in a multimedia format. Five complex, authentic activities were designed consisting of memos and other documents, to enable students to explore the resource within the parameters and constraints of a realistic task. The interface simulates the front part of a classroom with the resources located in full view (see Figure 1). The student accesses each resource by clicking on the appropriate part of the picture.

Figure 1: Main interface of the assessment strategies program

A study was designed to observe students' use of the interactive multimedia program and to investigate the effect of the situated learning framework on how students learn. Two preservice teachers were videotaped as they used the program and presented a report, over a period of three weeks' class time (9 hours). At the end of the period, each student was interviewed. Data was transcribed and analysed with the assistance of NUD•IST, a computer-based qualitative analysis program.

Authentic context

The authentic context presented to students was one of a physical and conceptual structure of a classroom which users were free to explore. The various media elements available to the user of the program provided authentic

BEST COPY AVAILABLE

data from a variety of perspectives. Students had access to more than 60 video clips, over 60 text files and over 20 graphic images and documents, as well as a notebook facility to record their own notes. A sufficiently rich and complex knowledge base was necessary to enable students to solve realistic and complex problems. Generally however, students did not recognise that they were working in a complex learning environment. This is consistent with Honebein, Duffy and Fishman's (1993) premise that it is not necessary to simplify learning environments to enhance learning, and that providing 'realistic levels of complexity' in a learning environment can help to make learning easier (p. 95). While the interface and navigational paths of the program were deliberately kept as simple as possible, the conceptual nature of the contents was far from simple. This was acknowledged by one student:

> I was actually surprised at how much you can learn from such a simple brief program. There was just so much in there that you could learn from. (Interview with Deborah)

The predominant feature of the context of the assessment program was that students appreciated the real-life relevance of the material they were using. They frequently pointed out the contrast between the authentic context presented in the program and the decontextualised approach:

> It wasn't like academics discussing the relative theories and things like that, which is what we get lot of at uni. It was actually teachers showing how they'd implemented it, and discussing it afterwards. (Interview with Glen)

Authentic activities

The activity was designed to incorporate all the uncertainty and unpredictability of an authentic task. Students were provided with a copy of a letter of complaint from a parent, together with a memo from the Principal requesting a plan of action to remedy the problem. The task was ill-defined. There was no summarising question or topic for the investigation, simply the presentation of the two documents. Students' first task was to work out exactly what they were required to do. Collins (1988) has pointed out that students often invoke 'suboptimal schemes' for remembering information and to help them cope with the day-to-day demands of school learning. For example, arithmetic students might conclude that any word problems including the word 'left' (How many did she have left?) are subtraction problems. One student revealed the 'suboptimal scheme' she used for 'finding the question':

> We had to read it four or five times to actually get out what it was asking us to do... because the actual question was in the middle, it wasn't at the bottom and it wasn't at the top, we sort of had to look through and go 'Oh there it is'. (Interview with Deborah)

This comment reveals that the student's standard procedure of looking at the beginning or end of an activity for the 'actual question' did not work in this case. The students spent considerable time not only identifying the requirements of the task, but also in breaking that global task into sub-tasks. There was active engagement in finding and defining these composite problems as well as solving them.

Expert performances

The assessment strategies program gave students access to expert performances in three ways. Firstly, the video clips of the scenarios being demonstrated in the classroom were generally performed by experienced teachers who were well acquainted with the use of the strategy. Secondly, students had access to the commentaries provided by 'experts' in the field of mathematics education and assessment strategies in the *Interviews* drawer of the filing cabinet. Thirdly, students were able to read the reflections and advice provided by third year student-teachers who were only one year more experienced than the students using the program. While students were generally very positive about the exemplary teaching provided in the scenario videos, none commented on the 'window into practice' or the social or cultural insights into classroom life that the video scenes might have afforded. They were very much focussed on the videos as demonstrations of the assessment technique in a real life context.

Multiple perspectives

The assessment program enabled students to access multiple perspectives in two distinctly different ways: one related to the way the assessment strategies were presented in the program, and the other to the task that students

437

were given to complete. The program presented a variety of perspectives on each assessment strategy, from the teacher's, student's, pre-service teacher's and expert's point of view. One student, comparing the program to a traditional lecture, indicated that the multiple perspectives provided many 'avenues to understanding':

> In a lecture you can't click onto the video and get the video to play. When you've got a huge lecture situation, the lecturers can't keep stopping and going ... Whereas with this it gives you so many avenues to understand it from. You may not understand the theory side but you can understand the scenario side and then find out what the teacher thought. There's just so many different ways of looking at that one strategy. (Interview with Deborah)

The task students were set as an investigation also required them to present a report which included implications for three different groups. Prompted by a complaint from a parent, the 'new teachers' at the school were asked to prepare a suggested plan for assessment in mathematics 'including benefits and problems for parents, students, and teachers'. The group did not complete the different perspectives required in this task beyond recommending a suggested assessment plan for the school. Nevertheless, there was much evidence to suggest that students viewed the material several times, in different ways, and used 'alternative routes of traversal ... criss crossing a topic in many directions' (Spiro, Vispoel, Schmitz, Samarapungavan, & Boeger, 1987, p. 188). Regardless of which pattern of use was adopted, students rarely used a linear or regularly systematic approach in searching the media elements. Both students spoke of looking at items more than once if necessary, going back over items, and investigating individual elements in greater depth.

Collaboration

While using the interactive multimedia program on assessment, students worked in small collaborative groups of 2-3 students grouped around each computer. Students perceived many clear advantages in working collaboratively. One advantage is that the completion of the task benefited from collaboration with another person, essentially that view that 'two heads are better than one'. A frequently mentioned advantage of working collaboratively was that the partner often helps by telling or explaining something that the student didn't know or understand. The view was also expressed that, at times, collaboration is essential to continuation of the task. In the absence of a partner, this support would be provided either by the teacher, or as one student pointed out, by 'annoying' the person on the next computer:

> The fact that if you're confused about something you can ask somebody and they're right there next to you. You don't have to put your hand up and wait till the teacher gets to you. And you're not ... trying to annoy the person that's on the next computer, ... you've got someone to ask. (Interview with Deborah)

This view sees collaboration as essential to learning, that it is sometimes obtained by stealth, and that it is given necessary legitimacy by the arrangement of students into small groups.

Reflection

In order to provide a learning environment which would promote reflection, the assessment program was designed primarily with an authentic context and an authentic activity to enable students to engage with the program and to reflect upon it in a meaningful manner. It was also designed to enable multiple entry points, non-linear navigation, and access to an electronic notebook to enable students to note their reflections and ideas immediately. Neither of the students overtly attributed the non-linear navigational aspects of the program as an aid to reflection, although this did appear to be a contributing factor to reflection. The findings suggest that the learning environment did allow students to freely reflect on their learning by providing them with a multimedia program and collaborative working arrangement which enabled them to return to experiences, attend to feelings and to re-evaluate the experience (Boud, Keogh & Walker, 1985). The students were able to share their reflections with each other and use the notebook facility to conveniently record them, confirming Ennis's (1985) belief that reflection is a social process.

Articulation

Students articulated their understanding of assessment strategies in two ways: the formal report to the staff meeting, and in their discussion with their partner as they used the program. Many interactive multimedia programs do not allow either form of articulation to occur. Students are assigned individually to computers to

488

work alone, and in so doing, the knowledge remains tacit. Lave and Wenger (1991) point out that being able to speak the vocabulary and tell the stories of a culture of practice is fundamental to learning. The students were aware of the difference between tacit knowledge and verbalised knowledge. One student pointed out the difference between 'knowing' and verbalising in a manner which suggests that the knowledge is incomplete unless it can be articulated, and that knowing 'in my mind' is little more than a good starting point for further research. The students were also clearly aware of the importance of articulation to learning. However, they almost invariably viewed articulation as an act of clarifying an issue rather than an integral part of the learning process itself. Counsellors and psychologists have long been aware of the importance of verbalisation in beginning to affect change in problematic behaviours. A frequently quoted psychological law of counselling is 'I learn what I believe as I hear myself speak' (Saunders & Herrington, 1995, p. 8). Similarly, Baktin (1986) contends that 'any true understanding is dialogic in nature' (cited in Brown & Campione, 1994, p. 267). The implication is that the very process of articulating enables development, refinement and awareness of thoughts:

> If you have to put something into words, you have to think. (Interview with Glen)

Students using the assessment package were also very much aware of the value of formally articulating their learning in presentation of reports to their classmates, or as Pea (1991) describes it 'creating rich conversational artefacts for discussion and presentation' (p. 65). Students were surprisingly positive and comfortable with the prospect of presenting a report to a larger group (given that fear of public speaking is often ranked more highly than fear of death in popular surveys) and in this sense, they may not have been typical. However, one student pointed out that reports to class were more and more becoming a standard feature of their university classes.

Coaching and scaffolding

From the analysis of the data, it is apparent that coaching and scaffolding is provided essentially from two sources: the teacher, and the student's partner in the collaborative groups. The teacher of the class being observed was thoroughly familiar with the program and its possibilities, and knew the requirements of the coaching and scaffolding role. The role of the teacher was seen as one which essentially clarified issues for students and was important because it saved time. It enabled the students in the study to proceed with the knowledge that their effort was 'on the right track' and that the support given to them was precisely at the point they needed it. The assistance provided by the teacher was essentially procedural on both content (e.g., Is it meant to be a written report?) and software (e.g., There's no sound on this video). In the lessons observed, students rarely consulted the teacher on higher-order questions related to the task. However, the arrangement of students into collaborative groups meant that the student's partner could provide a coaching and scaffolding role. This support was particularly evident in the higher order thinking related to the investigation the students were doing. The students were aware of the influence interactions with their partner had on the depth of their learning. For example, when asked to describe the advantages of working in pairs, Glen showed considerable understanding of the concept of scaffolding and how it relates to his own learning:

> If you've got somebody else ... you scaffold a bit. Like when you go 'Oh cool, this is what it means' and the other person, who might not have even considered it goes 'Oh yes' and then takes it a step further and you end up doing more indepth thinking about it. Otherwise I might just have a bit of a superficial look at it. (Interview with Glen)

Students were very positive about the supportive role their partner played, and clearly linked the arrangement of students into collaborative groups to the value of articulating their own growing understanding of the issues.

Integrated assessment

The assessment program included an activity which required students to propose new assessment strategies for the mathematics department in a school. It was this one activity which they investigated for the entire three week period, and it was this activity upon which they were assessed. Students were required to give both an oral and a written report of their proposal. When questioned about the value of a type of assessment which is closely tied to the use of the program, the two students were very positive about it. Both felt that such a close connection between activity and assessment meant that it was virtually impossible to 'regurgitate' information in a meaningless manner. Similarly, with the written report, they felt that an essay, had it been set, would have allowed a lot more 'drivel' as opposed to the tighter requirements of an authentic report.

Conclusion

This paper has described a preliminary evaluation of a theoretical framework for the design of interactive multimedia based on a situated learning model. In so doing, it has investigated the use of a multimedia program by two students, and their thoughts opinions and feelings about learning from this type of program. Early findings indicate that it is a successful approach enabling students to construct their knowledge about the topic in an effective, non-linear, and collaborative manner. This preliminary study is currently being followed by a more extensive evaluation of six students' use of the program, including an investigation into their practical use of assessment strategies in teaching practice in schools. It is hoped that the current and more extensive study will suggest many seeds for further research, both analytic and systemic (as described by Salomon, 1991), into the manner in which students learn from interactive multimedia.

It is proposed that roadblocks have been set up by interactive multimedia programs which seek to deny students any choice in how they progress, which try to control the nature of the interaction between the computer and the student, and which limit collaborative opportunities by insisting upon a single user at each computer. The multimedia program described here is an attempt to open up those avenues of understanding.

Abstract:
The use of CBI software to support the educational requirements of healthcare professionals, patients and students has been a continual source of research and application. However, little attention has been focused on the development issues central to CBI which support the needs of today's patients, who are beginning to play a more integrated role in their own health care. Such software must not only help to attain the educational objectives and requirements of the patient, but should facilitate the support of healthcare issues, trends and objectives of the environment in which it resides. In its development, we must not only address methods of instruction, educationally competent and functionally correct user-interface designs, but must identify, develop, utilise and annotate clinical relational data that flows across system management boundaries. To achieve the characteristics of educational integration and support the increasingly active and participatory role of the patient in clinical decision making, preferences and expected outcomes, computer-based patient education must be seen as *a technological support for clinical effectiveness*. The challenge of development must embrace important facilitators which aid the conceptualisation and evolution of this specialised CBI software. In this paper, we present a synthesis of opinion from various research arenas such as cognitive engineering, educational technology and medical informatics, with specific attention focused upon the evolution of the electronic book metaphor to support the user-centred, collaborative design of educationally integrated, computer-based patient education.

Introduction

As part of a PhD research collaboration between the Computer Science Department of the University of Wales, Cardiff, and Velindre Hospital (a specialist cancer treatment centre in Cardiff), we are developing a networked educational environment which can encapsulate and manage numerous multimedia computer-based patient education applications, integrated into Velindre Hospital's information-rich healthcare setting. The evolution of such an environment and the development of these specialised applications, present unique challenges. We have produced specialised *patient-knowledge management* software to develop and manage healthcare multimedia 'electronic books' which serve to support the increasingly participatory role of the patient in their own health care. At the heart of the development of these CBI applications and the evolution of the educational environment is a user-centred and collaborative development philosophy supported by a concept we term a 'metaphor vocabulary'. This is an evolution of the 'electronic book' metaphor which has become a much discussed development concept and design paradigm in the educational computing community. We believe the use of this vocabulary is an essential aid for user-centred, collaborative development of complex yet usable clinical CBI. Whilst a detailed commentary on our patient-knowledge management and development software is beyond the scope of this paper, we take the opportunity to discuss the importance of the 'electronic book' metaphor and its recent use. We then comment upon a suggested evolution into a metaphor vocabulary to support the development of more integrated, educational software for patients.

491

Summary of the Electronic Book Metaphor, Past and Present

Theory and Application

The electronic book metaphor is not altogether new. Philip Barker, in his book 'Author Languages for CAL' [Barker 1987] discusses two authoring software systems which utilised the book paradigm for educational software development and use. These date back to the early eighties. Otsuki and Takeuchi's 'BOOK' system of 1981, developed in Japan, was used to develop CBI applications which outwardly resembled books in that they included titles, content lists and indexes. These books could be grouped together into a library which allowed them to be accessed by author or title. ComCAL, developed by Donaghy in 1985, also used the electronic book metaphor and was written in Pascal. These books were organised into chapters and pages.

The traditional 'electronic book' metaphor allows the end-user and developer to conceptualise a CBI application as a computerised version of a traditional 'paper book' with additional characteristics such as hypermedia functionality, assessment and feedback. Until recently, graphical user interfaces were not capable of replicating a visual book on screen. With improved authoring tools, processing power, visual high resolution and graphics packages, it is now possible to build interfaces with a two dimensional book design as a backdrop to educational content. These applications can further mimic the paper book by providing a contents page at the start of the application and an index at the end [Benest 1991].

The proliferation of commercial educational software and authoring software which utilise the electronic book metaphor appears to amply justify the viability of an electronic book development paradigm. Successful 'off the shelf' education titles include multimedia encyclopaedias, complete literary works, classical music and composers, geography atlases, GCSE and A-Level revision books. The most successful beneficiaries of the book metaphor include interactive language titles which exploit the idea of the electronic book to the full [Barker 1994b].

Metaphors, Myths and Models

Barker and Manji [Barker 1991] describe the cognitive aspects and relevance of the electronic book metaphor. They see the metaphor as an aid to the formation of sets of conceptual models that learners apply to different learning situations. Conceptual models form part of the cognitive make-up of the computer user, providing the means by which a user understands and uses various computer systems. Barker and Manji go further in their discussion of metaphors by introducing the concept of the 'myth'. The 'myth' is a metaphor used at the interface level of a system to aid the conceptual model of the system to which the interface relates. The 'myth' enables the designer to actuate and orientate a user's cognitive activity. Where a metaphor does not exist at this level, they suggest that one may be designed according the user's cognitive framework of the real world. The authors imply a hierarchy comprising pages at the base level, chapters at the intermediate level and a single parent book at the summit. The 'page' contains the educational media.

Doubtless, few commentators could not have foreseen the rapid evolution of visual development applications of this decade, which make use of metaphors at both the development and user interface. Like many 4th generation visual development tools, ToolBook uses a specific metaphor-supported conceptual model; in this instance to present the developer and end-user with individual pages, each one relating to a single multimedia screen or frame which together constitute the 'application book'. Control code, modules and procedures can be placed in a 'control book' which is a parent to the application book being developed. Microsoft's Visual FoxPro utilises a 'forms' metaphor as an aid to the development of highly graphical interfaces to relational data tables. It would appear that the concepts of a 'myth' and the metaphor have been realised in commercial development software, implying that metaphors are relevant to end-users and developers alike.

The Electronic Book Metaphor and Integrated Clinical CBI

Medical Informatics and Educational Computing: Metaphors are Equally Applicable

'Metaphors communicate real-world analogies, and communication is at the core of what defines usability (*sic.* of clinical information systems). A 'mind map' facilitates communication by building a model in the user's mind' [Esterhay 1994].

'A metaphor is primarily a likeness or analogy to a concept that already exists within a cognitive framework' [Barker 1991].

Both of these informal definitions apply to the use of metaphors in the development of software. However, Esterhay's comments refer to medical informatics - specifically the development of clinical workstations, and Barker's comments refer to educational computing - specifically the development of CBI applications under the development paradigm of electronic books. The enthusiasm for the book paradigm (which includes study books, text books, encyclopaedias, guide books and others) is such that the authoring and evaluation of electronic books have been treated by educationalists specialising in educational software as a separate CBI development issue [Barker 1994a, Richards 1991, Collis 1991]. With some exceptions [Santer 1994, Mooney 1995, D'Alessandro 1993, D'Alessandro 1995], the benefits of the electronic book metaphor have so far received little attention in the field of medical computer based instruction.

As we will discuss, we believe this metaphor is as applicable to computer-based patient education in clinical environments as it is to computer based education for schools, colleges and commerce.

The Need for Metaphor-Supported, User-Centred CBI Development

Even before today's authoring software tools provided database connectivity to table based relational databases such as dBase and FoxPro, and true relational databases such as Ingres and Oracle, emphasis was growing on the use of more complex networked and distributed educational software systems. De Diana envisages the use of networked electronic books sharing resource and other networked facilities such as electronic mail [De Diana 1991]. Much recent attention has been focused on the World Wide Web for the availability of distributed educational resources [D'Alessandro 1996]. The Internet is not viewed as being an appropriate network medium for all forms of computer based education at Velindre Hospital. We are primarily interested in integrating computer based education into the information structure of the hospital which includes confidential patient data held in our own clinical information system. Owing to the confidential nature of patient information and the consent required for its use, the Intranet is also viewed unfavourably. We envisage our *educationally integrated* computer-based patient education, as characterised by the inclusion of patient data, protocols, treatment options, philosophy, organisation and clinical opinion, and support for healthcare issues and trends such as patient-centred decision support, informed patient consent to treatment and the production of tailored patient information. Internally produced CBI applications sharing confidential networked patient data with our patient information system, sharing educational resources and helping to meet external healthcare objectives, require a development process and conceptualisation of the end product which is fundamentally more involved and complex than traditional CBI applications that focus purely on educational objectives.

Suitable collaborative development philosophies, supportive conceptual models and development metaphors are of paramount consideration if the potential for computer-based patient education is to be exploited, applied and utilised.

Supporting the User-Centred, Collaborative Development of Clinical CBI

The extension of the electronic book metaphor to increase functionality and features has been well documented by Mayer and Mulder with their NEAT project [Mayer 1994] . Reference can also be made to the Calsa project of Barker and Giller [Barker 1994b]. Metaphor extensions not only encompass new features and functionality for CBI development. We argue that if the electronic book metaphor can be adequately extended to include a vocabulary of related metaphors which can accommodate both development and end-use of CBI software [fig. 1], it is possible to support collaborative and user-centred development. The result of a vocabulary of related metaphors is a 'metaphor dialogue' between those who are party to the collaborative development effort. In specialised, clinical environments comprising conglomerate, specialised units or 'firms', and varying levels of computing expertise amongst individuals, a metaphor dialogue can be an invaluable asset for promoting effective discussions across boundaries of working culture and computing experience. This facilitates: consortial development communication, an increase in the usability of the end product and a reduction in the risks typically associated with health care software development.

Figure 1: Extract from the Metaphor Vocabulary

The possibility of a development relationship existing between a metaphor vocabulary and collaborative, user-centred development is explored below.

The use of a user-centred approach to system design and engineering, and the resultant impact on human computer interaction has been well documented by a number of authors. Donald Norman comments that "..user centred design emphasises that the purpose of the system is to serve the user, not to use a specific technology, not to be an eloquent piece of programming. The needs of the user should dominate the design of the interface and the needs of the interface should dominate the design of the rest of the system.." [Norman 1986]. The requirement for a collaborative, user-centred design approach becomes more dominant as task complexity, conceptual image complexity and problems of user-understanding become noticeably more difficult to address. In support of user-centred design, Norman also discusses the use of conceptual models and a system image in response to the problems associated with the differences between the human and system facades of the user interface. Two mental models and one physical model are suggested by Norman such that the design of a system follows a consistent, coherent conceptualisation (a design model), and enables the user to develop a mental model of the system (a user model) consistent with the design model. To facilitate these models, the developer needs to construct an appropriate system image of the physical structure of the system. It is interaction with the system image that promotes compatibility between user model and design model. Norman also states that this places a severe burden on the designer, particularly as the system image needs to be explicit, intelligible and consistent.

Where user-centred design embraces a collaborative development philosophy, we believe the need for compatibility between Norman's various conceptual models is of primary concern since the end-user or product commissioner is active in all of three conceptual domains. Using our metaphor vocabulary and a highly visual development software, we have succeeded in producing an enveloping conceptual model called the 'conceptual development paradigm' which effectively maps the user model, design model and system image into a single conceptual framework.

As an example, the physical system relationship between CBI software and networked clinical data at Velindre Hospital can be viewed in terms of the open database connectivity which facilitates the use and annotation of data held in a clinical information system. The conceptual development paradigm uses the metaphor vocabulary to map this to a design model comprising access to external libraries of patient data which can be utilised by investigating the indexes (data entities) and their subheadings (data attributes) which catalogue the library resource structure. The user model comprises a conceptual view of the interface as a page of the electronic book which is not only decorated visually, but is also automatically re-edited when the reader 'turns a page' to incorporate up to date clinical data from external libraries of patient information.

The emphasis we place upon the importance of collaborative development is reflected by a number of authors from various research communities. The relevance of collaborative authoring of educational software has been considered in detail by Min and Rada in the context of computer supported co-operative work (CSCW) and the Dexter Groupware model for collaborative authoring and document re-use [Min 1994]. Collaborative authoring is seen as particularly relevant to the authoring of complex distributed educational software systems.

Nielson and Thomas comment on the merits of using a consortia model of software development to foster a collaborative approach as educational software becomes more complex in its design, distribution and use, and attention focuses towards networked educational resources [Nielson 1996]. Our metaphor vocabulary embraces the use of external clinical and educational resource, with sufficient vocabulary content to support collaborative discussions to this effect. In addition, we have been able to target expertise by using the metaphor vocabulary to support the definition of basic data structures before requiring system developers to build the necessary data tables and supplements to the existing clinical information system.

In the field of clinical informatics, a form of collaborative development where the end-user is invited to participate in design and iterative evaluation (particularly at the prototype stage of development) is termed user-centred development. Its importance is described by Nowlen et al [Nowlen 1994]. Nowlen outlines the difficulties of constructing intelligent clinical systems where understanding what the professionals need and understanding the techniques that can meet these needs has proved hard to master. One of the approaches Nowlen used in his own work includes user-centred development and supportive evaluation. Both of these concepts, Nowlen suggests, are seen as addressing the apparent problems of clinical systems failing to meet end-user requirements or being unusable in clinical conditions. Also in the field of medical informatics, Esterhay has focused on the use of metaphors to improve communication and, consequently, system usability. Metaphors are seen as an aid to the provision of prototypes which can be evaluated by all parties involved in the development process [Esterhay 1994]. Our metaphor vocabulary is extensive enough to describe both clinical and educational requirements in educational workstation development, is competent enough to provide support of consortia or group discussions, and is also used in the documentation produced in our development methodology to support iterative evaluation and discussion through the development process.

Collaborative development, user-centred design and the use of metaphors are all seen as catalysts for improved conceptualisation, communication, iterative evaluation, realisation and user appreciation.

Summary and Exploitation

We have discussed the importance placed upon the electronic book metaphor and the possibility of extending this in the form of a metaphor vocabulary which promotes a dialogue necessary for effective user-centred development. User-centred development is seen as potentially important for the development of integrated clinical CBI. At Velindre Hospital, we have taken advantage of this broad base of opinion spanning the research disciplines of educational computing and medical informatics to introduce a metaphor vocabulary supporting user-centred development within our knowledge management software.

At Velindre Hospital, we have employed a metaphor vocabulary to support the in-house development of a computer-based, multimedia awareness 'book' called ADV (Advisor) which promotes an integrated role for patient educational software. ADV is a male cancer advisory application used as an educational mediator between specialist cancer nurses and patients during counselling sessions. It informs male cancer patients about prostate, testicular and bladder cancers, clinical trials participation and aspects of male sexuality affected by cancer treatments, using video, sound, text and pictures. It also elicits information from patients about their preferences, concerns and expectations about their care, and produces tailored patient information documents. Patient feedback is stored as a supplement to the clinical information system. Collaborative development has comprised a specialist cancer nurse, CBI developer and has received input from clinicians specialising in cancer, and informaticians with knowledge of the information systems of the Hospital. The ability of a metaphor vocabulary to break down communication barriers between computer experts, the educational software developer and end-user has received encouraging responses. The ability of the metaphor vocabulary to define conceptual views of the application and the information resources of the hospital, (conceptual views which are common to the collaborative team regardless of computing expertise) has also been positively received. A full evaluation of this vocabulary is currently underway and early indications suggest that the metaphor vocabulary may be of particular benefit in allowing educational developers, clinical informaticians, commissioners and end-users to jointly conceptualise the specialised educational applications, and to conceptualise related concepts such as databases, entities, attributes, entity relationships and shared educational resource.

Abstract: The creation of cognitive conflict is one of the most effective ways to give learners' high motivation. Cognitive conflict can be created by providing a phenomenon which is different from a learner's idea or prediction: differences which are important to her/him. To use cognitive conflict for motivating learners, two factors are important: (1) the method to generate phenomenon, which includes differences for their ideas and (2) the ability to diagnose whether those differences are significant enough or not to create cognitive conflict. In this paper, first, we propose Error-Based Simulation (EBS) which is a method to create a behavior simulation reflecting an erroneous equation of a mechanical problem. We have confirmed, through experiments, when differences between EBS and a correct simulation weren't qualitative ones in "velocity" or "acceleration," a learner usually couldn't judge which behavior was correct. This paper also describes a diagnosis method of EBS with qualitative reasoning techniques.

1. Introduction

Motivation plays a crucial role in learning. The development of high motivation in learners is a key issue in education [Hatano 87]. Numerous investigations indicate that the creation of cognitive conflict is one of the most effective ways to give learners' high motivation. Cognitive conflict can be created by providing a phenomenon which is different from a learner's idea or prediction: differences which are important to her/him [Gagne 85, Osborne 85, Glynn 91] . Only differences which the learner can become aware of, arouse cognitive conflict. The learner is then motivated to correct her/his idea or prediction in order to dissolve the cognitive conflict.

To use cognitive conflict for motivating learners in a computer-based learning environment, two factors are important: (1) the method to generate phenomenon, which includes differences for their ideas and (2) the ability to diagnose whether those differences are significant enough or not to create cognitive conflict. We have proposed a method to create a behavior simulation reflecting an erroneous equation of a mechanical problem, in order to motivate learners to correct their errors [Hirashima 95a]. The simulation is called Error-Based Simulation (EBS). We have confirmed, through experiments, that EBS isn't always effective in arousing motivation for the correction of erroneous equations. In the experiments, learners who formulated erroneous equations were shown EBS. The results indicated that when differences between EBS and a correct simulation weren't qualitative ones in "velocity" or "acceleration," a learner usually couldn't judge which behavior was correct. In such cases, the learner's cognitive conflict was seldom aroused. For this simulation to be effective, EBS should be required to satisfy one or two conditions, "the qualitative difference in velocity" and/or "the qualitative difference in acceleration" [Hirashima 95b]

This paper describes a diagnosis method of EBS with qualitative reasoning techniques. First, by using qualitative simulation [Kuipers 86, Kuipers 94], the behavior of EBS is predicted and it is compared with the behavior of a correct simulation. When a qualitative difference is found, EBS is effective in arousing cognitive conflict. However, when qualitative differences aren't found, a parameter of which perturbation causes qualitative differences between EBS and a correct simulation is sought by using comparative analysis [Weld 88]. This qualitative difference is also useful in creating cognitive conflict. If this parameter cannot be found, EBS shouldn't be used.

Currently, a module which realizes the above management of EBS is implemented. This paper also discusses the effectiveness of EBS management through experiments.

2. Creating Cognitive Conflict with EBS

2.1 Methods to Create Cognitive Conflict

When learners' are corrected on their answers, it is not enough to simply tell them what the correct answers are.

BEST COPY AVAILABLE

Learners often just accept the corrected answers without really understanding their meaning and frequently continue to repeat the same mistakes. To prevent the same mistakes from recurring, it is essential that learners become aware of the significance of the errors [Resnick 82, VanLehn 92, Laurillard 93]. Creating cognitive conflict is one of the most effective ways to motive learners to understand and to correct the errors.

Several computer-based learning environments, especially in physics, use simulations for creating cognitive conflict [Murray 90, White 93]. Here, cognitive conflict is created by showing a phenomenon which is different from a learner's erroneous prediction. The framework of this method is illustrated in Figure 1. In the framework, it is assumed that when the learner has an erroneous idea, she/he predicts an erroneous phenomenon reflecting that idea. Based on this assumption, to show the correct phenomenon, it is useful to create cognitive conflict. When the learner thinks the difference is important between the correct phenomenon and the erroneous one, which is predicted by her/him, cognitive conflict is aroused and she/he is motivated to correct the error. We call this method "Creating Cognitive Conflict by Correct-Mapping."

The above method is most effective when a learner predicts an erroneous phenomenon. A learner, however, doesn't always predict an inaccurate phenomenon when she/he has an inaccurate idea. The learner often knows a correct phenomenon in spite of her/his erroneous idea. For example, in Dynaturtle [diSessa 82], a learner operates "turtle" and tries to move it following her/his prediction. When the learner has an erroneous idea, she/he fails to control it. The differences between the correct phenomenon, which is predicted by her/him, and the generated phenomenon by operations, often arouse cognitive conflict. The framework of this method is illustrated in Figure 2. We call this method "Creating Cognitive Conflict by Error-Mapping." Several training environments with simulation, for example, STEAMER [Wenger 87], use this method to create cognitive conflict.

Most learning environments using this method, however, only deal with errors of parameters. All phenomenon generated in the environments are following correct laws. When a learner puts erroneous parameters in a simulator, she/he is usually presented with unexpected phenomenon. Although the unexpected phenomenon is different from the learner's expectation, it is correct for the parameters. Therefore, only one correct simulator is required in such learning environments. We call this type of error-mapping "Parameter-Error-Mapping." The framework is illustrated in Figure 3.

EBS, however, can deal with an erroneous equation of a mechanical problem. In general, an erroneous equation means an error of rules which control phenomenon. With this definition, a specific simulator is required to reflect the erroneous equation to phenomenon. This framework is illustrated in Figure 4. Equations in physics are rules of object behavior. A correct simulator which is developed to generate simulation using correct rules, cannot deal with erroneous equations. We have proposed EBS to generate simulation reflecting erroneous equations. In other words, in the framework of EBS, rules used to generate behavior are different in correct simulation. We call this type of error-mapping "Rule-Error-Mapping."

Simulations generating by Rule-Error-Mapping are unreal ones. Therefore, the use of Rule-Error-Mapping should be more careful than the use of Parameter-Error-Mapping, which generates real simulations. In this paper, we also describe a management module of EBS in addition to EBS itself.

3. Error-Based Simulation and Its Management

3.1 Error-Based Simulation [Hirashima 95a]

EBS is generated by mapping an erroneous equation in formula-world to simulation-world. The EBS shows irregular behavior in contrast with the behavior of a correct simulation. The differences arouse cognitive conflict which motivates a learner to correct the error.

The method which reflects an erroneous equation onto the behavior simulation is called "Rule-Error-Mapping" (following simply called "error-mapping"). A mechanical component which can be set up as an equation of motion, such as a block, slope or platform-car, is called "object." Each object is given several equations constraining its mechanical attributes and behavior. These equations allow us to generate correct simulation. Currently, the error-mapping changes a value of a "velocity" or "acceleration" of an object by using the erroneous equation, and then generates EBS with the changed value. In the simulation, the object behaves in a strange manner and other objects behave normally.

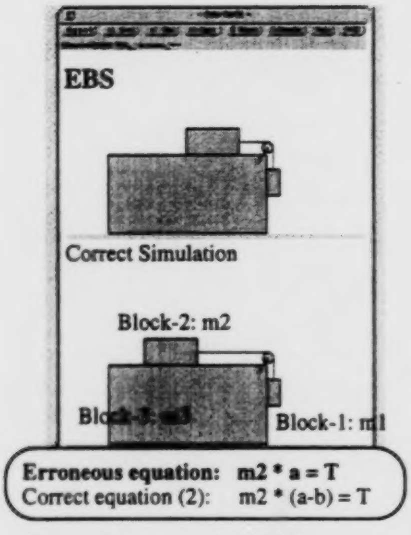
The procedure to generate EBS is divided as follows: (1) specifying an object to change the behavior (the object is called ER-object), (2) specifying an attribute to change its value for reflecting the erroneous equation (the attribute is called ER-attribute), (3) deriving the changed value (the value is called ER-value). When the dimensions of the unit system in the erroneous equation are wrong, it is impossible to calculate ER-value. Therefore, the coordination of the unit system in the erroneous equation is indispensable to generate EBS.

Figure 5 shows an example of EBS. The problem in Figure 5 is a three-blocks problem with one pulley. Each block can move without friction. Block-1 is restricted to move along the side of Block-3. A reactionary force exists between Block-1 and Block-3, and they move as one unit having a horizontal motion. When the vertical component of acceleration of Block-1 is "*a*" and the horizontal component of acceleration of Block-3 is "*b*," the horizontal component of acceleration of Block-2 is "*a-b*." Learners often formulate the erroneous equation "*m2*a=T*" for the horizontal movement of Block-2, instead of the correct equation "*m2*(a-b)=T*." The upper simulation in Figure 5 is the EBS for the erroneous equation and the lower simulation is the correct simulation. In the erroneous equation, the acceleration part is "*a*." It is used as the value of acceleration of Block-2. The correct value of acceleration of Block-2 is "*a-b*." In the EBS, Block-2 moves faster than in the correct simulation while Block-1 moves normally. Consequently, the distance between Block-1 and Block-2 is being narrowed. Because both EBS and the correct simulation are shown at the same time, learners can compare them easily.

The authors confirmed EBS was effective to correct these erroneous equations for learners through an experiment. However, for other problems and errors, EBS doesn't always visualize an error clearly. Therefore, a management function for EBS is required.

3.2 Requirement for EBS Management

The above procedure to generate EBS doesn't pay attention to the kinds of differences from a correct simulation.



Erroneous equation: m2 * a = T
Correct equation (2): m2 * (a-b) = T

Figure 5. An example of EBS.

Equation-A: ma = mg sin θ
Equation-B: ma = − mg sin θ
Equation-C: ma = mg cos θ
Equation-D: ma cos θ = mg

Figure 6. An Example of Mechanics Problem.

BEST COPY AVAILABLE

Occasionally, EBSs which aren't useful to visualize errors are generated. In Figure 6, when a learner sets up Equation-B as an equation of motion of the Block, the EBS based on Equation-B shows the Block ascending the Slope. The correct simulation based on Equation-A shows the Block descending the Slope. In this example, EBS visualizes the error clearly. When a learner sets up Equation-C, the EBS based on Equation-C only shows the Block moving in the same direction along the Slope as the correct simulation, but with a slightly different velocity and acceleration. In this case, it is difficult for the learner to judge which behavior is correct. For Equation-C, EBS shouldn't be used directly. However, when the angle of the Slope Ø increases, velocity and acceleration in the EBS decrease while in a correct simulation they increase. Such noticeable changes in behavior enable the learner to recognize the error.

Through these examples, in order to visualize an erroneous equation clearly with EBS, the authors assumed that EBS should include qualitative differences in "velocity" and/or "acceleration" against a correct simulation. Based on this assumption, an EBS-manager is required, as described below:

(1) EBS-manager can analyze the behavior of both EBS and a correct simulation qualitatively. It can also judge whether or not there is a qualitative difference in velocity or acceleration between them.

(2) When there aren't any qualitative differences, the EBS-manager can search for a parameter of which perturbation causes a qualitative difference in velocity or acceleration between EBS and a correct simulation.

Qualitative reasoning techniques are used to realize the EBS-manager. Before explaining its mechanism in detail, "qualitative differences" which contribute to recognizing errors are defined as follows:

Definition-1: There is a "qualitative difference" between two objects' behaviors when the qualitative values, (e.g., "plus," "zero" and "minus,") of velocity or acceleration of the objects, are different. For example, in Figure 6, the qualitative values of the velocity and acceleration of the ascending Block in the EBS based on Equation-B are "minus," while the qualitative values of the velocity or acceleration of the descending Block in the correct simulation based on Equation-A are "plus." Therefore, there is a "qualitative difference" between the EBS based on Equation-B and the correct simulation based on Equation-A.

Definition-2: There is a "qualitative difference" between two objects' changes in behaviors when the qualitative values, (e.g., "increasing," "steady" and "decreasing,") of the ration of their velocity or acceleration changes to a parameter's change (except time) are different. The qualitative values are called "qualitative directions." For example, in Figure 6, the velocity and acceleration of Block in EBS based on Equation-A increases when the Angle of the Slope Ø increases. When this happens, the qualitative directions of the velocity and acceleration are "increasing." The velocity and acceleration of Block in EBS based on Equation-C decrease when the Angle of the Slope Ø increases. Therefore, the qualitative directions of the velocity and acceleration are "decreasing." When this occurs, there is "qualitative difference" between the EBS based on Equation-C and the correct simulation based on Equation-A when the Angle of the Slope changes.

3.3 EBS-manager

The management process of EBS is divided into two phases. In Phase-1, the EBS-manager compares the qualitative behavior of the EBS with the one of a correct simulation. When a qualitative difference is found, the EBS-manager judges that the EBS is effective in arousing cognitive conflict and shows the EBS to a learner. When a qualitative difference cannot be found, it proceeds to Phase-2. In Phase-2, the EBS-manager tries to find a parameter of which perturbation causes a qualitative difference between the EBS and a correct simulation. When such a parameter cannot be found, the EBS-manager judges that the EBS shouldn't be used to create cognitive conflict.

3.3.1 Phase-1: Qualitative Simulation

First, the EBS-manager predicts qualitative behavior of the EBS by using QSIM [Kuipers 94]. The behavior is then compares with qualitative behavior of a correct simulation similarly predicted by qualitative simulation. When a qualitative difference is found, the EBS-manager judges that the EBS is effective in creating cognitive conflict.

QSIM derives the qualitative states consisting of the "qualitative value of velocity" and the "qualitative value of acceleration" based on an equation. For Equation-A, that is correct equation, both values are positive. In contrast, both values of Equation-B are negative. Qualitative differences are found between the behaviors of Equation-A and Equation-B. Therefore, the EBS-manager judges that EBS for Equation-B is effective.

3.3.2 Phase-2: Comparative Analysis

When a qualitative difference cannot be found by using QSIM, the EBS-manager tries to find a parameter by using comparative analysis [Weld 88] of which perturbation causes a qualitative difference between the EBS and a correct simulation. When such a parameter cannot be found, the EBS-manager judges that the EBS shouldn't be used to create cognitive conflict.

For Equation-C, the EBS-manager cannot find any qualitative difference between the EBS based on Equation-C and a correct simulation based on Equation-A by QSIM. In this case, by using comparative analysis, Ø is found as a parameter of which perturbation causes qualitative difference between the EBS based on Equation-C and a correct simulation based on Equation-A. Increasing Ø increases acceleration of the Block in the correct simulation, while increasing Ø decreases acceleration of the Block in the EBS.

For Equation-D, the EBS-manager cannot find any qualitative difference between the EBS based on Equation-D and the correct simulation based on Equation-A, by qualitative simulation. In spite of comparative analysis, no parameter is found as a parameter of which perturbation causes qualitative difference between the EBS based on Equation-D and a correct simulation based on Equation-A. In such a case, the EBS-manager judges that the EBS shouldn't be used to visualize the error. The way to treat this case is discussed in the next section.

4. Experiment

The EBS-manager has been developed on Sun SPARCstation10 with Japanese Open Windows Ver.2.0.1 and Lucid Common Lisp. Its effectiveness was evaluated through an experiment. Using the problem shown in Figure 6, EBSs for the erroneous equations (Equation-B, Equation-C, Equation-D) were shown to ten subjects who were college students in the engineering department. In each EBS case, the subjects were shown both the EBS and a correct simulation at the same time and were asked two questions: (1) could they judge which behavior was correct, and (2) did they feel the EBS was useful in motivating a learner to correct the error in the equation. Figure 7 is the example shown to the subjects where the EBS and a correct simulation were shown at the same time. The upper simulation is the EBS based on Equation-B. The lower simulation is the correct simulation based on Equation-A.

In the case of Equation-B, by qualitative simulation, the EBS-manager judges that the EBS is effective because it has qualitative differences from a correct simulation based on Equation-A. The EBS-manager shows the actual EBS to the subjects. Observing the EBS in which the Block was ascending the Slope, all the subjects recognized the strangeness in the EBS and could judge which behavior was correct. They also answered that this EBS was useful in motivating a learner to correct the error. This result suggests that the EBS is a promising method to create cognitive conflict for the error.

In the case of Equation-C, by qualitative simulation, the EBS-manager judges that the EBS isn't effective because it doesn't have any qualitative difference from a correct simulation, based on Equation-A. By comparative analysis, the EBS-manager finds Ø as the parameter of which perturbation causes qualitative difference between the EBS and a correct simulation. The EBS-manager instructs the subjects to change the Ø by direct manipulation, and generates the EBS and the correct simulation with the changed Ø. Observing the EBS in which increasing Ø decreases acceleration of the Block, all of the subjects recognized this strange phenomenon and could judge which behavior was correct. Eight of the subjects answered that this EBS was useful in motivating to correct the error. Two subjects answered that the EBS wasn't useful, indicating that the interface of the system should be improved to show the two EBSs, one being the original EBS and the other being the EBS with changed Ø, simultaneously. However, even these two subjects said the idea of the EBS is useful. These results suggest that the modified EBS is a promising method to help a learner correct his/her erroneous equation.

For comparison, the original EBS based on Equation-C with fixed Ø was shown to the subjects and all of them failed to judge which behavior was correct. They answered that this EBS wasn't useful in understanding an error. This fact indicates the importance of the EBS-manager.

In the case of Equation-D, the EBS-manager cannot find any qualitative difference either by using qualitative simulation or by using comparative analysis. Currently, the EBS-manager judges that the EBS isn't useful to visualize the error in Equation-D. The subjects were asked whether they had any suggestions: three of them

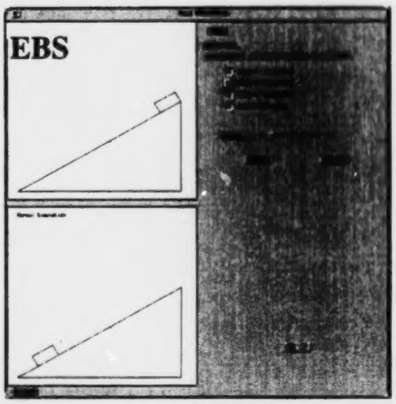

Figure 7. Example of EBS Shown to the Subjects.

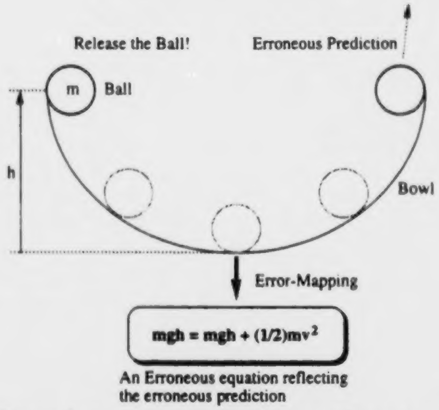

Figure 8. An Erroneous Prediction of Behavior and the Erroneous Equation Reflecting the Prediction.

BEST COPY AVAILABLE

indicated that changing the Ø down to zero (meaning Flat Floor) or up to 90 degrees (meaning Vertical Wall) causes a qualitative difference. When Ø becomes zero, the Block still moves at gravity acceleration in the EBS based on Equation-D, while the Block doesn't move any longer in a correct simulation based on Equation-A. When Ø becomes 90 degrees, the Block falls down at infinite acceleration in the EBS based on Equation-D, while the Block falls down at gravity acceleration in a correct simulation based on Equation-A. Although these are qualitative differences, changing a parameter to its limit cannot be treated by EBS-manager because DQ analysis treats only the perturbation that doesn't change in behavioral topology. Improving EBS-manager to be able to treat such cases is an important future work.

5. Conclusion Remarks

We describe a method to create cognitive conflict and its management. EBS is a behavior simulation reflecting an erroneous equation for a mechanical problem. The differences between EBS and a correct simulation visualize the error and arouse cognitive conflict. EBS-manager diagnoses and modifies EBS in order to use EBS effective with qualitative reasoning techniques.

One of the major future works indicated is to realize error-mapping from behavior prediction to equation. There are several cases in which it is more effective to map an error in behavior prediction to create cognitive conflict. This fact is explained with an example shown in Figure 8. A learner often predicts that the Ball released at the left edge of the Bowl jumps out of Bowl at the right edge. This is wrong. In this example, it is easier to explain the reason why the predicted behavior is wrong by using an equation. The explanation is as follows: a learner easily understands that the whole energy of the Ball at the left edge is "mgh", and she/he also easily understands that the potential energy of the Ball at the right edge is "mgh" because it is at the same height. However, if the Ball jumps out of the Bowl at the right edge, it must have the kinetic energy "(1/2)mv^2". As a result, a strange equation "$mgh = mgh$ + (1/2)mv^2" is derived where the energy of the Ball isn't conserved. The learner can then understand that his/her prediction is wrong by the equation more easily than by the behavior simulation.

Multimedia Learning Environment in Statics

Siegfried M. Holzer and Raul H. Andruet
Virginia Polytechnic Institute and State University
Blacksburg, VA 24061-0105, USA
E-mail: holzer@vt.edu

Abstract: We are developing a learning environment in the subject area of statics that combines physical experiments, interactive multimedia, and cooperative learning in the framework of experience-based learning [Kolb, 1984]. Statics is concerned with the computation of forces acting on bodies (solids or fluids) in equilibrium. The course is designed to promote the active engagement of students in learning. A review of the literature, which supports these activities, is presented and some multimedia learning modules are illustrated. We are using Authorware Professional to construct the multimedia program.

Introduction

> *...for the computer to bring about a revolution in higher education, its introduction must be accompanied by improvements in our understanding of learning and teaching.* Nobel Laureate Herbert Simon [Kozma and Johnston, 1991]

Simon's statement has been a reassuring theme in our search of principles and strategies for active learning to guide the design of a multimedia learning environment for statics. In the process, the course has evolved into a workshop style environment [Laws, 1991] that combines physical experiments, interactive multimedia, and cooperative activities in the context of experiential learning [Holzer and Andruet, 1996]. We are increasing physical experiments, developing new multimedia modules, and planning a service project to extend "learning by doing" [Dewey in Brooks and Brooks, 1993] from the classroom to the community.

In this paper we provide a background for experiential and cooperative learning, illustrate some multimedia learning modules, and present some preliminary results from a workshop learning environment.

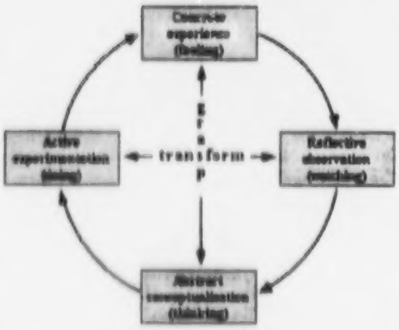
Experiential Learning

> *Learning is the process whereby knowledge is created through the transformation of experience.* [David Kolb, 1984]

Experiential learning, which is modeled after the scientific method, has its roots in the works of Dewey, Lewin, and Piaget [Kolb, 1984]. It focuses on the central role that experience plays in the learning process. Moreover, "learning from experience is the process whereby human development occurs" [Vygotsky in Kolb, 1984].

Although experience is essential to learning, it is not enough; one has to do something with it to construct knowledge [Piaget, 1954; Bringuier, 1980; Holzer, 1994]. This is reflected in Kolb's experiential learning model [Fig. 1], which displays the two fundamental activities of learning: grasping and transforming experience.

Each activity involves two opposite but complementary modes of learning. One can grasp an experience directly through the senses (sensory, inductive mode) or indirectly in symbolic form (conceptual, deductive mode). Similarly, there are two distinct ways to transform experience, by reflection or action. At any moment in the learning process, one or a combination of the four fundamental learning modes may be involved. It is significant that their synthesis leads to higher levels of learning [Kolb, 1984]. We found it helpful to view the four-stage learning cycle as a spiral in time that extends beyond a session. For example, a concept or principle may be developed or applied in different contexts, at different times, and through different learning modes.



Concrete experience (feeling)
Reflective observation (watching)
Abstract conceptualization (thinking)
Active experimentation (doing)
transform
grasp

Cooperative Learning

> *...early evidence suggests that students who work in small groups, even when interacting with high-tech equipment, learn significantly more than students who work primarily alone.* The Harvard Assessment Seminars [Light, 1990]

Cooperative learning is not a new concept [Ercolano, 1994]. Extensive research, initiated in the late 1800s, has demonstrated significant advantages of cooperative learning over competitive and individualistic learning in various learning characteristics; these include [Johnson et al., 1991]: high-level reasoning; generation of new ideas and solutions; motivation for learning; personal responsibility; and student retention.

Cooperative learning provides structures [Kagan, 1990] to engage students in meaningful activities that can be shared with others [Papert and Harel, 1991]. Meaningful activities include authentic activities that represent future tasks and problems and are rich in learning resources [Beichner, 1993]. Kagan [1990] encourages teachers to use a range of structures to enhance their usefulness in the cognitive and social learning of students.

We have been experimenting with some structures and have found think-pair-share [Lyman, 1987; Habel, 1996] and variations of pair activities effective in the classroom: Students **think** about a problem individually to organize their thoughts; they form **pairs** to share and discuss their solutions; they **share** and discuss their findings with another pair or a larger group. It is encouraging to receive positive minute paper [Cross, 1991] feedback from students: "I think our group works well together. I have learned a lot from working with them." "I realized how much more I learn when I help people."

Learning Environments

> *I see more clearly than before that the path to motivating students is the joy of creation, exploration, and discovery. I see also that these processes are social in nature and that shared experiences in class and through teamwork projects are vital.* [Shneiderman ,1993]

We taught and evaluated a section of statics in the workshop format for the second time last fall. We met in computer labs where two students shared one computer. A session was generally divided into three parts: (1) We started with short group activities, a warm-up problem, to focus on problems or questions that surfaced in homework, weekly quizzes, or minute papers; (2) this was followed by mini lectures (10 - 15 minutes long) and cooperative activities; (3) at the end of the session, students were asked to reflect and answer questions about the day's lesson and activities (minute paper). Our learning resources included physical models of simple structures, a multimedia program that was used in lectures and group activities, pencil and paper for manual activities, and a board to aid discussions.

The biggest challenge, especially in the first course, was to achieve a good balance among various activities. This is crucial for students who are not highly motivated or skilled learners; a rich, active learning environment can become overwhelming. This potential problem can be reduced as follows: (1) Give students the opportunity to master one unit of learning modules before moving to the next [Terenzini and Pascarella, 1994]; (2) frequently place learning modules in context of the course framework and objectives, the students' background, and real engineering problems; and (3) provide frequent feedback. It is also important to stress the students' responsibility for learning and the benefits of helping one another learn.

In the second course, the students adapted quickly to the new learning environment. The following comments selected from minute papers reflect their attitudes: "Groups/pairs are great to work in." "Good to have a few minutes to think/reflect before conversing with partner." "Interesting learning concept; good to be part." "Computer and partner interaction makes class seem easier. More ideas are aired with this environment." "The group activities allow for personal interaction and verbal comparison. Then reverting to the computer to see the answer and diagram really helps." "Computer is very user friendly and set up well for learning." "The computer diagrams really helped me to understand the concept of components." "The program that we are using is so easy to operate and understand. Technology, isn't it wonderful." "I feel like I am getting a good grasp on the material." " Seeing it on the computer helps so much." "I enjoyed answering the questions of my partner." "I am actually enjoying this class."

Multimedia Learning Modules

Figure 2 introduces a two-part session where students first develop the principle of transmissibility and then apply it to compute member forces in trusses. The development of transmissibility involves the first three stages of experiential learning [Fig. 1], called in this context experiment, analysis, and transmissibility.

1. **Experiment.** Students work in pairs to determine the tensile force in member 2 [Fig. 2] and indirectly the compressive force in member 1 [Fig. 3]. This approach was motivated to find an inexpensive way to measure the compressive force in a physical model of a truss; a compression force meter costs about 10 times as much as a spring scale.

2. **Analysis.** Free-body diagrams (FBDs) are constructed of joint c to observe that the joint can be balanced either by the compressive force applied by member 1 [Fig. 4] or the tensile force applied by the spring scale on the other side of the joint [Fig. 5]. The objective is to discover that one can move a force along its line of action without disturbing equilibrium (the principle of transmissibility). The Note and force resolution appear in Fig. 4 if the value for F_1 is entered twice incorrectly and in Fig. 5 if "no" is entered in response to the question "Is joint c in equilibrium?"

Further details about this two-part session are presented in the electronic version of the paper.

Summary

Workshop Statics, a laboratory-based learning environment for statics, is being developed. It includes physical experiments, group activities, and interactive multimedia in the framework of experiential learning. This learning environment is described, and some learning modules from a session on trusses are presented.

Acknowledgment

Funding for this work was provided by the NSF to SUCCEED (Cooperative Agreement No. EID-9109053). SUCCEED is a coalition of eight schools and colleges working to enhance engineering education for the twenty-first century. The work was also supported by a grant from the Center for Excellence in Undergraduate Teaching at Virginia Tech.

Abstract

Technology integration plans must demonstrate a strategic fit between institutional goals and those of the technology plan. Ideally, the technology plan will flow naturally out of the strategic institutional plan. This paper outlines a planning process useful to assist institutions in planning for technology integration. It describes a participatory process which builds on institutional contexts and reflects institutional values. It is a process that builds institutional support and ownership, with the capacity to be self-sustaining and responsive to a changing environment.

INTRODUCTION

Educational leaders have a responsibility to make decisions which establish purposes, goals, objectives and outcomes of their educational enterprise; they design the mechanisms by which goals will be achieved; and, they develop procedures for monitoring and evaluating achievement of those goals.

In institutions where actions align with these decisions, progress is made with clear focus and purpose. In educational systems where misalignment occurs between goals and actions, results are demonstrated in short-lived innovations, obsolete curriculum, and incompatible instructional and organizational practices and policies.

Increasingly, the public demands that educational institutions demonstrate decision-making processes and implementation strategies which are responsive to public need and accountable to public scrutiny. Economic realities and technological challenges are rapidly reducing both society's and government's tolerance for educational systems that have actions that do not seem to fit with what its stakeholders value.

In the province of Alberta, many of the thirty post-secondary educational institutions are currently involved in developing institutional technology integration plans in response to the Government of Alberta's recent initiative to create a $30 million funding envelope dedicated specifically to enhance the province's adult learning system through the application and use of communications and information technologies. These technology integration plans must demonstrate a strategic fit between institutional goals and those of the technology plan. Ideally, the technology integration plan will flow naturally out of the strategic institutional plan.

This paper outlines a planning process useful to assist institutions in planning for technology integration. It describes a participatory process which builds on institutional contexts and reflects institutional values. It is a process that builds institutional support and ownership, , with the capacity to be self-sustaining and responsive to a changing environment.

ORIENTATION TO TECHNOLOGY INTEGRATION

Technology is defined by its use. In an applied field such as education, the worth of instructional and learning technologies has been determined and measured by their practical application. This estimation of worth is determined by the user. So it is with technology integration plans. Their worth will be determined by users and by their "fit" with whatever teaching/learning views users hold.

What learners and practitioners value will determine how technology is used. And those who value technology in education hold that technology is one of the best mediums available to improve instruction, increase accessibility, increase interactivity, empower students, and at the same time, constrain ever-rising costs. It follows from this perspective, then, that technology is regarded as a tool that has the capacity to change how teaching and learning happen within an organization.

In most cases, educational institutions want and expect technology to be catalyst for change, and a vehicle to make those changes happen. There is an expectation that learning and instruction will improve with technology, that opportunities for learning will be increased, and that barriers and limitations to access will be reduced. There is an expectation that technology will change the culture of learning.

It is not surprising, then, that much time and effort should be devoted to planning for technology integration in a manner that ensures institutional values are recognized and that they direct how the technology integration plan will be realized.

APPROACH TO THE PLANNING PROCESS

Generically, strategic planning involves knowing where you are at as an institution, then planning for where you, as an institution, want to be--usually three to five years into the future. Components of a strategic plan may vary, but generally they include an assessment of the forces external to the institution that influence and have the potential to impact the institution's plan; an examination of the internal institutional environment, including its mission and goals statements, current and previous business plans, formal and informal planning documents, organizational structure and culture (climate), and resources; an assessment of needs (staff, student, administration, and community); and, a determination of both long-range and short-term goals and objectives for the institution.

This kind of strategic planning process, one we have found to be successful, necessarily involves flexibility and includes growth and changes. As technologies change, so do the requirements for students, for administration, faculty, support staff, curriculum and resources. The challenge for educational planners is to provide an environment that enables and supports changing learning and teaching processes.

Our approach to facilitating technology integration planning is based on our knowledge and understanding of instructional design, policy planning and educational leadership. We believe the planning process can be a valuable and constructive learning experience for all participants. We work closely with those assigned the task of planning and preparing the planning technology integration document--usually an internal Technology Integration Planning Committee. Together, as a planning team, we establish a framework from which to view technology integration and from which to highlight environmental, organizational, resource and support considerations which impact successful implementation of the plan. We find that this strategy builds commitment to the process and ownership of the final outcome.

What follows is a strategy for successful technology integration planning:

STAGE ONE - SETTING GOALS AND OBJECTIVES

The first step in the planning process is to clearly articulate, or have available, clearly articulated institutional goals. These evolve out of what institutional leaders, participants, and stakeholders value. Technology integration planning processes often involve a questioning of the fundamental vision statement of the institution to determine what is really valued, what it is that the institution wants its teachers and learners to take away with them when they leave the institution. What knowledge, skills, attitudes and values does the institution within its larger educational community believe its clients should learn?

The vision and mission statements of the institution form the foundation for the technology integration plan. For example:

STATEMENT OF CORPORATE VALUES AND BELIEFS

These statements are intended to act as the foundational principles on which the organization intends to base its planning processes, goals, objectives and strategies to achieve those objectives.

Here are a few generic examples:

We value quality, therefore,
we will provide services and resources which are reliable, relevant, and cost-effective.

We value success, therefore,
we will measure individual and group efforts and recognize successes.

We value resourcefulness, therefore,
we will optimize use of existing and potential resources, services and expertise.

STAGE TWO: DETERMINING ORGANIZATIONAL STRUCTURES AND SUPPORTS

A cursory profile of the institution's organizational structure, programs and current technology resources can usually be constructed through a review of institutional documents. Reviewing reporting lines and main service units is also important.

A review of the institution's current capacity to resource and support extensive technology integration is required. This includes an overview of current technologies in use or soon to be in use, as well as an assessment of institutional learner and staff support services. Curriculum development and delivery mechanisms should be examined. In addition, the institution's past accomplishments in technology integration should be documented.

Institutional documents and service units to review may include:
Mission Statement
Organizational Chart(s)
Business Plan(s)
Previous Planning Minutes
Facility Services
Planning Services
Computer/Learning Technology/Library Services

Student Services

An evaluation of program needs should specify the level of student access to technology resources that must be provided to meet student needs, as well as minimum entry-level competency and skill sets. This evaluation should include numbers of courses and programs, numbers of students enrolled in courses and programs, completion rates, and the amounts and types of resource requirements (including human resources) needed to successfully support courses and programs.

An institution should also carefully assess the ways in which it is currently using various information technologies in instruction so that it can plan to meet projected needs from the basis of current capacity.

An inventory of existing resources is required to identify deficiencies and redundancies. An assessment of resource supports should include a comprehensive inventory of the resources that the organization/institution already possesses that can be applied to assist faculty to teach and students to learn, recognizing that teaching and learning are to certain degrees reciprocal processes. Such an inventory should catalogue not only current technology resources, such as the number and type of hardware and software, but also other supporting resources, including technical staff, programming support, related media and library resources, computing capacity, faculty and staff expertise, and training materials.

STAGE THREE: DEFINING ORGANIZATIONAL CULTURE

Following a reading of the mission and foundational statements, organizational structure and supports, a critical step in strategic planning for technology integration is to determine the needs and perspectives of students, faculty, professional staff, support staff, and administration. Since technology integration can be viewed from many perspectives, it is important to assess the range of perspectives as they exist across institutional staff, management and executive.

Most often we conduct focus group sessions with instructors, students, executive and community members, for instance. Interaction and exchange among participants is important and useful to clarify issues, to understand competing points of view, and, where possible, to reach consensus. While gathering data for this stage, we invite participants to discuss the institutional context, climate, and organizational structure which will influence technology integration at the institution. Issues which emerge from these discussions are addressed with the Planning Committee. Together with an analysis of the organizational supports, this information is used to form the foundation on which the goals and objectives of the Technology Integration Plan evolve.

At the institutional level, faculty may assist in advising which skills students need to be successful in academic studies, in workplace performance, and in social/cultural development. These skills are usually specified in terms of credentials and competencies required for program completion. And although skill requirements should be reviewed regularly, constant review is essential when integrating technological skills, since these skills change so quickly. Updates and revisions to program requirements should clearly address levels of technology skills and competencies for each program.

An assessment of the skills required of students to succeed in an increasingly technological and competitive workforce can also be determined with assistance from prospective employers and employment agencies.

At the individual level, students should have input into determining their needs. Education and training should be done in consultation with students. With increased expectations being placed upon students to take more responsibility for accessing and managing their own learning, students need to have opportunities to express their needs, which should then serve to inform decision-making processes regarding the development of programs. Students can give vital information as far as what they perceive to be their levels of readiness, and capacity for manipulating new knowledge and skills.

Faculty and staff needs should be considered in terms of the skills and resources they require to assist students to achieve learning objectives. As methods of instruction are affected by technology, faculty and staff need to develop the competencies and skills to be able to use technology resources effectively in their practice.

Determining faculty needs is a complex process that relies heavily on faculty and staff to identify their own needs for training as well resources to facilitate training and instruction. While there can be no substitute for the input of professional faculty, professional staff, and support staff, some care must be taken to separate needs from wants.

STAGE FOUR: ALIGNING TECHNOLOGY INTEGRATION GOALS AND OBJECTIVES WITH INSTITUTIONAL GOALS

The alignment of the institution's overall strategic plan with the proposed Technology Integration Plan is imperative. Technology should support the institution's mission, goals and objectives, not determine them. Guided by the Strategic Plan, we customarily facilitate a session with the Planning Committee to develop a clearly articulated mission for technology integration, including the goals and objectives. This preliminary foundation directs all subsequent technology integration action plans. The Technology Integration Plan should have a foundational statement.

The following is an example:

"The College will use information technology effectively to create and support accessible and purposeful education and training opportunities designed to empower learners with the knowledge and skills to meet the challenges of the 21st century."

It is from the foundation statement that long-range goal and short-range objective setting can be written. These goals and objectives serve as guideposts to monitor and to evaluate progress.

It is important to recognize that developing goals and objectives for integrating information technology must take place within the context of other organization/institution planning processes. Only some of the goals and objectives established for the organization/institution as a whole, will be pertinent to information technology integration. When the goals and objectives of the institution are not congruent with the technology integration goals and objectives, it may be necessary to change previously stated goals and objectives to reconcile with changing technology and environmental conditions.

Once the long-term goals for information technology integration are established (achievable over the next three to five years), specific short-range objectives covering one to two years can be outlined. These objectives are then developed into specific projects and implemented as part of the operational component of the Technology Integration Plan.

Short-range objectives must be specific enough to be measurable. They are the final piece of the strategic plan that provides the specificity necessary to create projects which assign tasks, allocate resources and indicate the person, persons, or units responsible for conducting activities that lead to the accomplishment of definable outcomes.

The following are examples of goals and objectives:

Value: We value equality, therefore, we will strive for universality of resources and services.

Goal: Having equitable, effective and efficient information technology connectivity between all campuses.

Objective: To provide all campuses with baseline standards of telecommunications connectivity.

Action: Establish baseline standards of connectivity across all campuses.

Action: Assess each campus for connectivity needs (hardware, software).

Action: Prepare 3-5 year plan to implement telecommunications connectivity.

STAGE FIVE: DEVELOPING AN EVALUATION FRAMEWORK

An evaluation framework should be established for the entire Technology Integration Plan. This serves as a template to assess the Plan's progress and provides evaluation guidance to the various action plans. A framework includes all outcomes and the qualitative/quantitative evidence (in general terms) considered valid in achieving those outcomes. We facilitate a work session with the Planning Committee to determine outcomes and indicators. The following framework provides an example:

Goal 1: Increased and improved access to educational opportunities and services for adult learners

Objective 1.1: To increase opportunities for adult learners to access a diversity of learner support services, course and programs within their community

Outcome 1.1.1: Strategies are developed to acquire necessary resources/telecommunications for 1997/98

Indicator: Institution has developed partnership agreements with various private-sector industries

Indicator: Regular discussions are held with telecommunications service providers

Indicator: Community resource group has been established to organize fund-raising activities

CONCLUSION

Implemented wisely, technology integration not only provides students and teachers with various technologies, it positions technology as integral to the teaching learning process. Technology integration means that technology becomes integral to how business is done in an institution. It becomes embedded in curriculum objectives and in student outcomes. It becomes part of the everyday practice of how teachers teach and students learn. Strategic planning for technology integration allows the technology integration plan to align and support institutional values and goals. Without a strategic fit, technology integration plans sit outside institutional "will" and fail to be enacted.

SToMP: A Dynamic Approach to Courseware Development.

Abstract: SToMP (Software Teaching of Modular Physics) is a comprehensive software package designed for use in introductory level undergraduate physics. It provides the student with carefully written scripts augmented with activities, simulated experiments, references, glossary, historical material, and media clips which are displayed in an easy-to-use format exploiting the multi-windows computer environment. The material includes self- and assessed-tests for each module and an array of tools (calculator, spreadsheet, grapher etc.) which can be accessed from any point within the package. Two modules have been completed to date: Measurement and Uncertainty, and Waves and Vibrations. Other modules are in various stages of preparation.

This paper looks at the pedagogic rational for the SToMP system, and discusses modes of integration into existing courses. The system is dynamic, and is able to subsume new developments, some of which are described.

1 Introduction

Computers have been used in Physics for many years for many purposes, and attempts have been made for over twenty years to use them in the teaching of physics (e.g. Hinton 1977, Boardman et al 1988 and Wilson & Reddish 1992). During this time, however, no one method of using computers to enhance the teaching and learning of physics has emerged as a universal solution, and no two physics departments seem to use computers to aid teaching in the same way. This paper briefly discusses the problems of the introduction of IT-based teaching methods and why their use has remained marginal. It then introduces the Software Teaching of Modular Physics (SToMP) approach to meeting the needs of current problems in undergraduate physics teaching and learning. This approach has been developed by a consortium of academics within the Software Teaching of Modular Physics project. SToMP includes an efficient development environment, a consistent student interface and an integration mechanism that is widely applicable.

SToMP courseware takes advantage of all available computer-based media types and is inherently open to teacher and student. However, it has established guidelines and standards by which the media can be integrated in a structured manner and used to direct learning within prescribed curricula.

2 The SToMP approach

Conventional science teaching usually involves the following student experiences,

- lectures and seminars, augmented in some cases by video and demonstration.
- tutorials and problem classes.
- laboratory work, often linked with practice in the presentation of information.
- individual problem solving and essay writing, often linked with assessment.
- project work, often linked with the use of information sources.

From a student's point of view these can often form a set of only vaguely linked aspects of the same subject. Topics within a physics course tend to be compartmentalised, and laboratory experiments are often badly out of step with the presentation of the appropriate theory in lectures. The use of an appropriate delivery mechanism for a topic, or the inclusion of a new student activity at an appropriate point, is hampered by the rigid structure of course modules imposed by timetabling, logistic or other constraints. These sorts of problems are particularly relevant to the introduction of computer-based materials into existing courses that are already tightly constrained by staff commitments and limitations in student contact hours. Also, many departments are experiencing difficulties in finding funds to equip laboratories for large first year courses and are turning to computer based simulations (dry labs). With the timetabling constraint thus removed, these 'experiments' can be integrated into the courses at their proper time.

From the student's point of view, the introduction of a new computer based component to a course, in addition to existing activities, will not necessarily be taken seriously unless it is clearly an integral part of a course [Laurillard 1993]. This usually means that there has to be an obvious link with the course assessment.

The SToMP project has attempted to address these problems by providing a richly linked set of multimedia documents, interactive experiences and assessments that can be used as a replacement for some components of existing courses. The flexibility of the environment can also help improve the necessary conceptual linking between the disparate aspects of a course.

3 SToMP, a highly integrated system.

Each SToMP module comprises a complete and open learning environment that contains all the material needed for an in-depth study of areas of physics covered by that module. Two modules have been completed so far, Waves and Vibrations, Measurement and Uncertainty, and others such as Optics are under development. The completed modules contain over 100 hours of study material that can be used in place of conventional lectures as the principle teaching vehicle of a course. SToMP resources are best augmented by the usual tutorial support mechanisms and may be further enhanced by locally produced materials.

A SToMP module is logically structured into blocks which are further subdivided into units, each of which has a sparsely written but didactically complete teaching script. This leads the user through required subjects and arguments in the order required for suitable concept development. Modules are also provided with a rich resource of background material including sections from appropriate text books, video and audio sequences, pictures, animations, assessment material, a glossary, and other reference items such as data books and biographies. All the material is structured and indexed, and may be accessed via several information retrieval mechanisms. In addition there are a large number of interactive physical simulations and experiments that are introduced from the scripts together with documents describing how they can best be used [Fig. 1]. Students on a set course are expected to access the material by following these scripts. The layout of these provides consistent navigational cues to the importance of the linked material. The teaching strategy emphasises active involvement, with students being directed via questions through activities in a choreographed investigative manner. As part of this teaching strategy, scripts also contain problems which can require users to access other documents and resources in a more open-ended manner. The material included within each module is intended to be a superset of that which would be appropriate for any given course. This redundancy of material helps ensure flexibility of use, and is assisted by the built-in tutor's-notes files, which are designed to be edited by each course tutor.

Unit 1.6
Introduction to the *LCR* Circuit Activity

If a capacitor is discharged through a circuit containing an inductor and a resistor, the charge on the plates of the capacitor oscillates. Unlike the case of

press 'Play' to close the switch and start the oscillations. The oscillations of the ammeter and meter needles are shown immediately.

You can change the amount of damping by using th slider to change the value of the resistance. You ca change values of *L* and *C* by going to the 'Options'

Figure 1: An interactive physical model of a series LCR circuit, with meters and oscilloscope, together with a descriptive introductory document.

In addition to the resources and activities described above, the SToMP environment also contains an integrated set of subject-specific tools that can be used in conjunction with other features for problem solving or for project work. These include calculators, a simple spreadsheet, a graphing package, a word processor, and a data conversion utility. Using these, the student is encouraged to see SToMP as a mechanism for 'doing' physics as well as learning about it.

4 Integrating SToMP into existing courses

The advantages of the 'complete environment' approach become clearer when the details of course integration are considered. The system can be used as a direct replacement for lectures and tutorials instead of creating a need for additional contact or laboratory time. The role of the teacher then changes from lecturer to mentor, so that there is more time for one-to-one or one-to-few discussions and explanations and less time need be spent on preparing the details of course presentation. The system uses a range of techniques to present theory and to relate

BEST COPY AVAILABLE

it to the real world, and access to these resources is totally under the users control. This implicit tailoring to the needs of each student leads to self-paced progress that can match the learning style of each individual. The impersonality of the student's interaction with the computer may provide an additional advantage - students are sometimes hesitant about admitting ignorance to their tutor, but are less inhibited about accessing remedial help on a computer. It is important to emphasise that the material is open to students to add their own links, and to the tutor for adding both documents and links. At the simplest level, empty shell documents (tutor's notes) are included for the lecturer to provide study-guide advice to the institution's own students. At the other extreme, additional documents can be added incrementally and linked in to provide locally relevant emphases.

This integrated approach is a step beyond the piecemeal approaches often adopted in the guises of Computer Assisted Learning, Computer Based Learning, Information Technology in Education, etc. This system includes activities with relevant scripts containing descriptions and theory, problems and tests, and with appropriate background material being easily available. This creates the required environment for effective use of these resources that would otherwise need explicit definition by the teacher. The use of a standard user interface maximises the ease-of-use of the many components of the package, whilst the sophistication of a Windows based system supports the high degree of integration that the SToMP style requires. A multi-tasking environment encourages the use of a wide diversity of tools and on-line information sources within the learning activity.

5 SToMP use of windows

The windows user-interface is an important aspect of the SToMP learning environment. In a conventional (non-computing) learning situation, a student refers to several documents in one session, e.g. a text book, lecture notes, and the working of a problem, or, in the laboratory, the experimental equipment, the experiment instruction sheet, and a laboratory notebook. The windows interface implemented with a sufficiently high resolution monitor now supports this multiple document concept adequately, and such a multi-tasking interface is crucial to the effective use of the SToMP materials, which are designed to require several documents to be visible at the same time. For example, a test question may require a model to be used which in turn needs its own introductory text to be readable.

It is unfortunate that the early versions of the PC windows interface were available to the majority of users only on small, very low resolution monitors. This has had the detrimental effect of encouraging the 'misuse' of the interface by restricting applications to being run 'full screen', that is, to habitually take up the whole screen area with one application. It is only since the advent of higher resolution and larger size monitors that PC users are beginning to use their resources as effectively as UNIX windows users have since its inception.

An important factor for developers is the high quality and increased ease of use of the tools available for creating windows applications as compared to earlier DOS-based compilers. These not only enable quick and easy access to all the commonly required windows features but also support mixed language development by means of libraries of utilities or applications that are only linked at run-time (Dynamic Linked Libraries - DLL's). There is also a well defined and simple-to-use 'help' compiler, that allows for the speedy preparation of user support for each application.

Another factor that is contributing to the effective development of this style of integrated learning package is the emergence of standards for the presentation of the different media types within the windows environment. Despite the wide variety of hardware implementations of PC's, including the different sound cards and screen driver hardware, materials prepared to these standards perform in similar ways on different machines. In addition, and this is another important feature of the SToMP package, user institutions can prepare their own additional material of any media type, confident that it will integrate with the rest of the package in a seamless way. The

Microcosm™ Document Management System[1] used by the SToMP project allows such incremental additions to the linkbase to be achieved with minimal effort.

The windows style of interface is thus clearly an important enabling feature of the SToMP style of learning environment that requires users to access several related documents simultaneously. This use of windows can be much more than just the ability to have several documents open on-screen at one time. It can involve the copying of text, data, graphics, or other information from relevant sources into destination documents being prepared, for example, as private notes or as an assignment, or data into a spreadsheet for analysis.

6 Looking to the future.

The features that have been included in the SToMP materials to date are limited to those we have been able to either find or produce, that are of appropriate quality and style. The usefulness of this or any similar environment will be improved, in principal, if we can include additional features (e.g. more background reference material), more scientific tools (e.g. an integrated algebraic manipulator such as MAPLE), further experiment simulations, or the additional modules required to provide a complete coverage of the first year syllabus. The usefulness of this style of environment will also be improved if the necessary computing skills to use it were acquired by students before reaching higher education. The lack of these skills seems inappropriate given the almost universal use of computers throughout all information based employment. We suggest that computer skills (touch typing and common interface usage) should be added to the basic skills that are a core part of secondary education. This would make a significant impact on the efficiency of use of computers in higher education, and on the accessibility of integrated packages such as SToMP.

One of the most important developments of SToMP is currently the extension of the integrated assessment mechanism. SToMP modules include not only self-evaluation questions within scripts (a useful didactic device that has been increasingly adopted in text books in recent years) and investigations which require the student to use the SToMP tools to answer questions related to the relevant module, but also automated tests with the question styles ranging from simple multiple-choice identification, through pair-matching from lists, to problems requiring a numeric input. In the self-test mode these tests are important as a means for student's self-evaluation and are particularly appropriate in a self-paced learning environment. In assessed mode they are an obvious means by which teaching efficiency can be improved without sacrificing quality and, if summative even at nominal levels, would motivate the students to use the material thoroughly. We are currently increasing the number and quality of both self and assessed tests within the SToMP materials, and we are also improving the security of the system for assessed tests.

It is interesting here to note the heavy use made by mass education institutions (e.g. The Open University, UK.) of machine-based continuous and examination assessment. The economics of such methods are compelling when student numbers are high, as they must be when the course presentation mechanisms are expensive and capital intensive (as they are in projects such as SToMP).

With the emergence of 'complete courses' available via a computer as described here, the issue of access to machines by students is another factor of significance. Different institutions are adopting different strategies to achieve this end, from 'giving' a computer to each student (as at Brighton University UK), requiring that newly entering students have one (as at Acadia University in New Brunswick), through to providing 24 hour access clusters. Whilst the actual mechanism is not too important, it is obvious that there is a closed loop in which the investment has to be justified by use, which in turn leads to more investment, until the ratio of machines to students reaches 1:1. This would still not solve all the problems, however, because of the two apparently conflicting requirements - that students can work at home with their computers, and also are able to work in supervised laboratories.

---

[1] Microcosm is a registered trade mark of Multicosm Ltd., Southampton, England. http://www.multicosm.com/

There is a distinct convergence between the approach we are adopting within the scope of the SToMP packages and the rich linking that is now implicit in, for example, World Wide Web or Hyper-G [Andrews et al 1995]. We might speculate on the opportunity of augmenting a local learning environment (with sets of documents and links) with a more comprehensive set of documents. This could enrich the overall range of learning experiences without necessarily introducing significant time penalties or diluting local autonomy.

Looking a little further into the future, the use of artificial intelligence to improve the learning experiences of users of packages such as SToMP will conceivably challenge the quality of teaching obtained at Universities that use individual student tutoring. In a lecture, the pace of presentation is controlled predominantly by the lecturer who is unable to cater for all requirements. As the ratio of staff to student improves, the matching of presentation rate to acceptance rate improves, but only as the ability range of the group narrows. One student with a skilled tutor will learn at the optimum rate because the tutor will match presentation and discussion to the perceived rate of concept development, often attempting to 'stretch' the student. The current style of SToMP provides material at the rate demanded by the student, but does not provide much incentive for an able student to go beyond the stated minimum requirements. An artificially intelligent (and highly interactive) system would be able to match a student's requirements in a way that maximised their individual learning potential.

Abstract: This paper describes the design and development of the prototype of a hypermedia application to enhance Spanish phonetics instruction for American and Hispanic students. In addition to meeting the various objectives of a phonetics course, the current application remedies the inadequacy of current Spanish phonetics methodology and fulfills the various needs of a dynamic and diverse student population taking Spanish phonetics at the college level. Traditionally, Spanish phonetics learning is supported by textbook and audio cassettes alone. This methodology is not efficient enough in providing a learning environment that encourages students to develop an introspective awareness of speech. In this paper, we will show how we improve Spanish phonetics instruction by integrating various powerful features of advanced authoring systems into the application.

1. Background

"Phonetics is the systematic study of human speech-sounds. It provides means of describing and classifying virtually all the sounds that can be produced by human vocal tracts" [Catford 1988]. Having a basic knowledge of phonetics is indispensable to any person who works with language. The teacher of languages needs the theoretical and practical knowledge of phonetics to diagnose the pronunciation errors made by students and to devise the means of correcting them. Students of languages also need the same knowledge to help them self-monitor their pronunciation.

The Spanish phonetics course is set up to meet the following goals. It aims to 1) assist in improving students' pronunciation through self-monitoring and recognition of common problems demonstrated by American-English speakers, 2) help students associate the sounds of the language with spelling, 3) expand their knowledge of the various dialects of the language, and 4) introduce them to the field of phonetic and phonological analysis.

Although it is possible to gain a good theoretical knowledge of phonetics through reading, it is the ability to capture the differences between various sounds through listening and manipulating articulators in the vocal tract that establishes the foundation of a deep understanding of the subject. Traditionally, students taking Spanish phonetics are rarely taught to contrast sounds through listening or consciously controlling their articulators. A phonetics class emphasizes on the discussion of the sound system more than gaining practical knowledge about it. Students are often left to imagine what a sound is like. They do it either by notes from the lectures or explanations in the textbook. Sometimes they associate the sound with a sound that they are familiar with. Audio cassettes have been a major device used in the classroom to demonstrate sounds, and they have also been available to students for outside the classroom. But, due to the limited capacity of the cassette player, it is difficult to locate a specific item without rewinding cassettes back and forth many times. The result can be frustrating and time-consuming. Moreover, it creates an unpleasant interruption to the learning flow. Consequently, the demonstration of sounds through a cassette player is usually conducted at once at the end of a lecture. It usually covers a long list of items and several exercises of various purposes. This strategy generally does not produce a good result. An alternative approach such as live demonstrations has also been adopted by instructors. However, bringing informants to the classroom is not always feasible since finding them and scheduling their visits are difficult tasks. Besides they are no longer accessible to students after the class.

In many cases a crucial difference between two sounds may be too subtle to be detected by the ear of a speaker of a certain sound system. Under such a circumstance, repetitions are undoubtedly mandatory. The students taking Spanish phonetics at the college level have very different backgrounds. There are both native speakers and non-native speakers. There are also beginning graduate students and upper-division undergraduate students. In accordance with their background, their strength on sound distinction and their paces on sound capturing can vary. For instance, when certain English allophonic variations seem to be indistinguishable to native speakers of English, they are distinct to native speakers of Spanish and vice versa. A psychological factor also needs to be taken into account when conducting listening or pronunciation exercises in the classroom. Some students would feel embarrassed if they made mistakes or if they were slower in a classroom setting. On the other hand, while native speakers of Spanish do not have the need to improve their pronunciation of Spanish, non-native speakers do. Furthermore, due to the complexity of articulatory movement, many students have difficulty grasping a concept by reading the textbook alone. This is true even when the language barrier is not a contributing factor.

Due to the lack of adequate and efficient tools to address the various needs, training beyond intellectual comprehension of Spanish phonetics has not been given enough attention. This situation calls for a solution.

2. Program Overview

2.1. Content

The phoneme /s/ is selected to demonstrate the design of the prototype of this application [Fig. 1]. The corresponding orthography rules are chosen to be in the first lesson because they are the basis of Spanish phonetics. Before starting a lesson on a phoneme it is important that students, both native and non-native speakers, have an understanding of the relationship of spelling to the spoken language. Contrary to English, this relationship is almost entirely regular in Spanish.

One of the objectives of the articulation lesson is to provide a very concise explanation of articulation for every allophone of a phoneme. Another objective is to help users visualize the physical process of articulation through animations describing and simulating the movement of articulators synchronized with narration and sound. It aims to help students who have difficulty visualizing the articulation process through ordinary textual explanations. It also encourages them to explore and experiment with their own articulators at the stage of trial and error in a private setting. When used by instructors, it can also be a teaching aid. This prototype program has covered the variations of the pronunciation of the phoneme /s/ (predorsal /s/, /s/ aspiration, /s/ deletion, and apical /s/, etc.).

Figure 1: Program Structure and Path

For each variation of the pronunciation of the phoneme /s/ there is a corresponding lesson on listening practice. It substitutes the function of audio tapes to provide samples of dialectal pronunciation in various phonological contexts. Using this, to repeat an item only requires a click of the mouse. It also makes comparing and contrasting sounds faster and easier as students can easily jump from one point in the program to another. In many cases same sets of words or sentences are chosen as examples so that users can easily compare different dialectal variations of pronunciation by contrasting them. It also offers an easy recording and play-back device to allow users to compare their pronunciation with a native speaker's pronunciation.

The lesson on pronunciation points out pronunciation problems commonly committed by American students and also provides model pronunciations. In addition, it offers an easy recording and play-back device to allow users to compare their pronunciation with the model. In this prototype two exercises are included focusing on correcting the use of erroneous pronunciation [z] for the letter z and for the letter s within words that have English cognates.

The Quiz gives students an opportunity to check their comprehension of the material covered in the whole course under one phoneme. It consists of three sub-tests. The first test serves as a pre-test that evaluates intellectual comprehension of the subject. The questions are either textual or concern the movement of articulators demonstrated by animation. Users will be advised to pass the first test before going on to the subsequent tests. The second test is a listening test on sound distinction at the word level. The third test evaluates the sound distinction ability at the sentence level. Both tests allow users to hear the words or sentences being tested as many times as they wish. Every time users enter the second or the third test, the program will randomly select one question out of five from each question bank. The questions are carefully formulated so that no obvious patterns are detected. That prevents students from guessing through the tests.

2.2. Semantic Structure

To help students accomplish their particular objectives, the program offers six different pathes under a phoneme and each has a course title reflecting its function: Complete Course, Orthography Rules, Articulation, Listening, Pronunciation Practice, and Quiz. Each course can be accessed individually. Therefore, students who only want to go over the listening exercises on /s/, do not have to go through every lesson in the program. Hence, each user can target his/her personal objective and choose a path to follow based on his/her own pace. The instructor may also concentrate on an individual student's need and assign a corresponding task through a path.

The Complete Course is a path allowing access to all the materials covered under one phoneme. It targets users who wish to preview, review, or reinforce the learning of Spanish phonetics in an individualized way. Although it follows a predefined path, the user has the freedom to move from any point in the system to any other s/he wishes. This is accomplished through either the default navigation features of each screen or the hot links on the detailed sub-menu, both of which will be explained in detail later in the section on navigation. Research has shown that users are less likely to feel disoriented or lost when there is a predefined path that narrows their options for navigation [Zellweger 1989]. Thus the path is predetermined from the instructor's perspective on how lessons can be best learned.

2.3 Navigation

From top to bottom, the program contains two menu screens. When a user enters the program, the first menu s/he encounters is the main menu, from where s/he will select a phoneme. In this prototype only one phoneme (/s/) is available for access [Fig. 1]. Subsequently a sub-menu screen appears, which contains a list of six radio buttons corresponding to the six pathes (or six courses) [Fig. 1]. As soon as the user clicks on one of the path units from the list, a detailed sub-menu containing a list of the corresponding lesson screens will appear at the right side of the current screen. The user can either click on the start button to start the lesson screens contained within the selected path (course) in a linear way or s/he can click directly on the lesson screen that s/he is interested in from the detailed sub-menu. This makes each lesson screen within a path accessible individually. This means that if a user has to abort the program in the middle of a course, s/he can restart right from the point where s/he left off.

Under the articulation path, a projector icon is displayed on certain screens to suggest that those screens contain animation on articulation. This enables instructors to locate them easily for classroom demonstration.

Within each path (course), using the default navigation feature of the authoring software, the user can follow a course both forward and backward one screen at a time, backward to the very first, or forward to the last screen. S/he can also open up a list of the screens being accessed and jump right into any one of them. In addition, s/he can leave the course and go right back to the sub-menu or use search function to locate a specific screen.

3. Program Features

3.1. Narration

Narration is used in the program whenever applicable since it takes less effort to listen than to read a text. However, it is used in congruence with visual display to facilitate the processing of information [Hoogeveen 1995]. For instance, a flying graphic, which is in textual format, corresponding to the point in narration, will appear on the screen to enhance the learning effect. On the other hand, the transcript of narration is available through selecting the show button.

3.2. Animated Texts Synchronized with Narration

As mentioned in the previous section, one of the multimedia features we include in this program is the synchronization of animated texts and narration to simulate a live lecture. This feature is used when simple texts are needed to exemplify points in the lecture.

3.3. Animated Graphics

Graphics showing the side-view of vocal tract have been widely used by phonetic books for pedagogical purposes. In our program, graphics of this nature are also adopted but added with other features. We use animated arrows as well as animated colored shapes on articulators to clarify and emphasize points in the lecture. In addition, to simulate the process of articulation we have used animated graphics along with concurrent pronunciation. It is suggested by Johansson that our visual system is developed to handle continuously changing information rather than static pictures [Hoogeveen 1995]. This favors the inclusion of time-based data, such as motion pictures. It is also shown that student's oral production would benefit from the simultaneous decoding of auditory data and sagittal representations [Lilly 1995]. Animated graphics and digitized sounds are thus chosen in this program. They will show how the mouth or articulators interact and shape up on affecting the air stream to be stopped or released through the mouth or nose along with the movement of vocal cords. Recent technologies allowing the exact synchronization of sound and animated graphics offer the possibility of demonstrating a supposedly simultaneous activity among vocal cords, articulators, and the flow of air, thus providing more realistic images of the articulatory process. Since a more realistic representation of information seems to lead to more natural arousal [Hoogeveen 1995], such simulated oral production, which is closer to real-life experience, may stimulate student's interest in experimenting the production of sound.

3.4. Hypertext

The transcripts of narration is hypertext-enabled. When the user clicks on a linked-text, a pop-up glossary explaining the terminology will appear. The text window closes when the user clicks anywhere on the screen.

4. Lessons Learned

4.1. The Selection of Software

Like all the other multimedia projects, the first question we faced was which software tools should we use for the project? Naturally, the search started from going through different authoring tools. The requirement for the tool is that it is easy enough for a non-programmer to use. Yet, it is powerful enough to allow all our program features to be developed. Quickly, we eliminated Visual Basic and Powerbuilder which require a lot of programming skills and are not fully integrated with some multimedia elements such as animation and video. After doing some research, Macromedia Authorware came to the top of the choice. Authorware provides a very simple interface to allow developers to create programs by drawing flow charts. It is easy and powerful for most of the cases. However, in the cases that require complex logic, some programming experience is required. Another reason that we selected Authorware is its' seamless integration with Macromedia Director. Director is a tool favored by a lot of animation and video developers. The integration of Authorware and Director eliminate the long existing limitation between authoring tools and video clips. For most of the authoring tools, the video clip is a separate entity. No communication can occur between the authoring program and the video clip except the basic play and rewind actions. Authorware and Director break this limitation by allowing Authorware to pass certain events (mouse click or key press) to Director. It opens up great freedom for application developers to design their products. Another reason that we have selected

Macromedia Director was because of its easy control over the exact synchronization of sound and animated graphics.

The greatest challenge for most in-house multimedia developers is the graphics. Most developers are not artists. How can we design a beautiful screen with the absence of the artist? CorelDraw and Macromedia xReses are the life savers of this project. CorelDraw is a comprehensive drawing tool. One of its' components is CorelTrace, which retraces the outline of the scanned in bitmaps and allows modification of the traced outline. xRes is an image painting and editing tool. Combing both tools, all the pictures in the magazines or books can be easily digitized and converted to the desired images.

Compared to the other multimedia elements, sound is the easiest element to control. Sonic Foundry's Sound Forge was used to edit sound files and to eliminate the noises created during the recording process.

4.2. Original Interface Design

User interface design is usually under the constraint of the software capability. For example, the original design of this project was to make use of a tree-like interface such as the Microsoft explorer in order to provide easy access to each lesson screen and to show an updated indication of the lessons being accessed. This type of interface structure is more exhaustive and the user does not need any provisional jumps in order to decide which further step to take. Unfortunately Authorware does not provide an easy mode of implementation. We therefore redesigned the interface in such a way that navigation efficiency is still maintained.

5. Summary

Spanish phonetics class plays an important role in helping students acquire needed knowledge and skills in differentiating sounds and in correcting pronunciation errors. The new computer hypermedia technology has made it possible for educators to develop appropriate application programs to fulfill students' needs as well as to correct the inadequacy of traditional teaching methodology. This paper has discussed the relevant issues of Spanish phonetics instruction and has described an effort to enhance the traditional teaching methodology. That effort has been made by developing a hypermedia-assisted application that takes advantage of the powerful features of current authoring systems. The development of such project suggests that the current technology may be properly used to meet the instructional needs for certain subject areas. Similar projects are thus welcome and the educators should be encouraged to develop their own applications.

Video E-mail: Hybridising Two Technologies Offers the Best of Both Worlds

Alistair Inglis
Flexible Learning Environment Unit, Royal Melbourne University of Technology, Australia.
ainglis@rmit.edu.au

Abstract: A pilot implementation of the concept of video e-mail is described. The purpose for which the system under development is intended is the provision of prompt assignment feedback to students studying visual art through open learning. The system being developed employs a combination of high speed digitisation, video compression; and MIME encoding to transmit digital video over convention e-mail networks. This paper describes the design principles employed, the developmental approach and the progress that has been achieved on the project so far.

Introduction

Many distance educators have been excited by the possibility which has been offered by the recent rapid advances in digital video technologies of using desktop video conferencing for the delivery of distance education programs to students in their homes. However, what many distance educators do not realise is that the data stream required to support high quality full-motion video is much larger than most telecommunications links can carry.

The digitisation of video generates data at an amazing rate. As an indication, digitising a full-frame, full-speed, full-colour video generates about 100 Mb per minute of data. When capturing to disc, as occurs in the creation of multimedia productions, such large volumes of data quickly fill the capacities of data storage media. In a communications environment, this flow exceeds the capacity of all but the most expensive data communication pathways. One way in which these capacity limitations are ameliorated is through the use of digital compression.

Video compression is now being used extensively for the inclusion of video segments on CD-ROMs. It is also starting to be used for inclusion of video clips in World Wide Web databases. However, the concept of video compression was first developed to support low bandwidth video conferencing. Video compression technology has therefore been evolving for more than a decade. Notwithstanding this, even the best available technology is still insufficient to support good quality full motion desktop video over telephone lines. It is still not practicable, therefore, to offer video conferencing amongst students in their homes.

By comparison with digital video, electronic mail is a mature technology. Electronic mail has been used in distance education as a routine means of communication between teachers and students by some institutions for more than a decade. This technology has been found to be both reliable and functional. Furthermore, despite its comparative simplicity, e-mail technology offers some advantages compared with video conferencing for distance education support. It is an asynchronous form of communication and therefore does not require teacher and student to be available at the same time. It can be carried over low data rate links and therefore can serve a more dispersed student population. It is economical to establish, maintain and use and therefore can be made available at much lower cost.

The difference between what can be accomplished within a desktop computer and what can be accomplished over a network reflects a generational gap between the relative stages of development of computer compared with data communications technology. Data can be moved around within a computer must faster than it can be moved from one computer and another. Furthermore, data can generally be transmitted much more easily within a local area network than within a wide area network. This generational gap will take time to close. However, in the meantime, there is the potential for creating some new and interesting possibilities by hybridising technologies. Combining digital video and e-mail technologies represents one such hybrid.

However, most people regard the concept of sending video over e-mail as being technically impractical even though standards exist for this type of transmission. However, what limits the value of the concept is the relatively small amounts of video that it is possible to send at a time.

At the Royal Melbourne Institute of Technology work is currently underway to investigate the practicability of combining video and e-mail technologies to support courses offered by distance education. The particular application which is forming the context for the investigation is the provision of feedback on student assignments in fine art. This work is being supported by a grant from the Open Learning Agency which is the brokering organisation responsible for Australia's open learning program.

Implementation of a full video e-mail system implies that users of the system are given the ability to generate and transmit video messages. This is problematic at the present time because the capture of video requires specialised hardware and processing capacity which is not available from typical computers found in the home. In the particular application chosen for this pilot project one-way video is acceptable. The use of a one-way transmission has the further advantage that the limitations of 'receiver' work stations to be compensated for by the greater power of the 'transmitting' work station. The project which is about to be described employs this approach.

Outline of the basic concept

Producing compressed digital video recordings is often quite tedious and time consuming. Adapting the standard approach to the production of video e-mail would make the concept unworkable. For the concept to be practical it needs to be simplified. Two ways of simplifying the process are to standardise the capture variables and to automate the capture/transmission sequence. In the case of the target application variables such as lighting and exposure can be standardised by using a constant field of view. Automation of the process can be achieved by bringing all the basic functions under the control of a small applications package running on the computer. The applications package can also manage a database of students' names indicating whether or not each student had the capacity to receive e-mail messages and if so, what the student's e-mail address is. If the student possessed an e-mail address, then the control application would create a standard e-mail message, add the video file as an attachment, and dispatch the message to the address. If the student didn't have an e-mail address then the control package would send the video directly to tape.

The concept of video e-mail involves four distinct processes: video capture, video compression, e-mail encapsulation, and video replay. Each of these processes requires its own specialised hardware and/or software. For the concept of video e-mail to be workable, all of these processes must be able to function together. However, to understand how integration of the functions can be achieved, it is necessary to understand how they function individually.

Video capture

Video capture hardware and software has been available for desktop computers ever since the advent of interactive multimedia. Initially, video capture was achieved through the addition of plug-in boards. However, as the popularity of multimedia increased has grown, a number of mid and high range desktop systems have appeared on the market which provide all the features needed for capture of video images and sound. The quality of the resulting images and sound does depend to some extent on the capabilities of the individual system. However, it is possible to obtain quite good quality sound in machines of quite modest cost.

Video compression

The device used to compress digital video is known as a 'codec' (compressor decompressor). Video compression can be accomplished either in hardware or in software. Hardware codecs compress and decompress at a faster rate than software codec. However, video which has been compressed with a hardware codec generally, although not always, also requires a hardware codec for decompression. For the type of application being considered here, it is necessary to use a software codec for decompression. To use a hardware codec would require that every student acquire a suitable codec as such codecs are not incorporated into most current generation systems.

Software codecs differ greatly in the degree of compression they offer. There is a trade-off between the degree of compression offered and the quality of the resulting image — as a generalisation one can expect that the greater the compression, the poorer the image.

Software codecs are installed at the operating system level. Apple provides several codecs with the Quicktime extension which is included with every Macintosh sold today. However, the best compression ratios can currently be obtained with codecs based on fractal technology and such codecs are at the present time sold separately.

E-mail encapsulation

E-mail systems were originally developed to transmit text-only messages. With the development of multimedia, methods, of transmitting other types of information were needed. In recent times a new protocol has been developed to handle multi-part documents [see Rose 1993]. This is called MIME. MIME includes a specification for transmitting video attachments. Users of the World Wide Web rely on MIME every day — it is incorporated into the helper applications which confer on Web browsers much of their functionality. MIME specifies the way information should be encoded and also ensures that it is handled appropriatly in The appropriate approach to transmitting video as an e-mail attachment is therefore to use a MIME compliant e-mail client.

Video replay

For it to be practical to use video in off-campus teaching students must be able to view video files when they arrive. Fortunately, with today's computers this is not such a problem provided that one is prepared to compromise on quality. Macintosh computers now come equipped with everything needed to replay a Quicktime movie. The software needed to replay a Quicktime movie on a Windows system can also be downloaded from Apple's Web site. However, playing movies on a PC does require the availability of a sound card such as the Soundblaster card. While these are now being to support games, they are by no means universal.

Students can't, of course, all be assumed to have the same type of computer and unless an institution decides to prescribe what computer a student must have in order to study a subject provision must be made to support a range of systems. The reality is that the Macintosh provides a more robust development environment for multimedia. Furthermore, the Macintosh has, at least in Australia, a strong following in education. What this implies is a need to support both Macintosh and Windows users. In this project, the need to operate in a cross-platform environment was taken as a 'given'.

Supporting cross platform is not as difficult as might at first be imagined. Current generation Macintoshes come fully equipped to play Quicktime movies right out of the box, and the software that gives them this capability — the Quicktime extension and Movieplayer application can be installed on all machines running System 7.0 or later. In trials conducted in the course of this project, satisfactory performance was obtained on an six year old Macintosh LC II.

Proving the concept

Recognising the critical dependency of the project on the capacity to compress the captured video sufficiently that it could pass through an e-mail system, it was decided that some initial investigations should be made of the performance we could expect to achieve.

Initial estimates indicated that it would be optimistic to expect to be able to capture and transmit more than two minutes of video at a time. Theoretical calculations based on typical compression ratios suggested that 2 minutes of video ought to be able to be compressed to under 5 Mb. This is still a very large file to try to send via e-mail. On the other hand, it seemed that a video that was much shorter than that would be likely to be of little educational value. How useful a two minute video clip would be was also open to question. It was therefore decided to perform some tests to ascertain whether the information that assignment markers considered important to communicate could be captured within the target two minute limit.

The tests were conducted by timing the recording of what was considered by the assignment markers to be the appropriate amount of feedback and then looking for ways in which the recording could be brought back within the target limit. The first attempt to record feedback took about four and a half minutes. However, with practice the recording time was able to be brought within the two minute limit. These tests showed that it was possible to capture a surprising amount of information in a two minute period provided that one was adequately prepared and the material that was being recorded could be laid out beforehand. If these conditions were not satisfied, it might take two to three times as long to capture the same amount of information.

Selecting a platform and development environment

Because of the rapid developments that are occurring in the technologies associated with multimedia, it was considered that the most appropriate approach to take to designing the system would be to base the design on a series of building blocks. By breaking the design of the proposed system down into its major components, and then loosely interfacing these components through computer control, each of the components can be optimised for the function it is meant to perform. The system as a whole can then be upgraded by replacing individual components as technology advances.

Evaluation of the alternative hardware options indicated that it would be simpler to construct a system based on a Macintosh than a Windows platform. The tighter integration, the better built-in capabilities for video and the greater inherent reliability of Macintoshes make these machines much more suitable platforms for development of a system which cannot afford to make heavy demands on technical support.

Having determined that the best choice of platform for developing a video capture system would be a Macintosh (or Macintosh clone) it was a relatively simple choice as to which model to select. At the time when the choice needed to be made only two Macintosh models offered the power and features that were needed. These were the 8500 and 9500 models. However, while the 9500 offered greater processing power, the 8500 provided video-out and well and video-in capability. This feature is needed if captured video is to be recorded to tape.

Locating a suitable video camera initially presented some difficulties. The type of video camera which is now found in the consumer electronics market is a complete camera-recorder system. However, despite the high degree of sophistication of these units, few provide any facilities for external control and none appear to provide the ability to control the recording functions. However, what was needed here was a small good quality camera and separate recording unit which could be independently controlled. The consumer electronics market does not offer such products. Eventually a suitable camera was found in the form of an industrial camera manufactured by Panasonic. An industrial video recorder manufactured by Panasonic was also chosen for capturing the video on tape. This recorder has an RS-232C interface for enabling all the mechanical functions to be controlled by computer.

In the past, the type of system integration being sought here would have required the development of a piece of dedicated software in a high level language such as C, C++, or Pascal. This would have necessitated the investment of a substantial amount of a programmer's time. Today, an alternative option is available — the integration of existing applications by means of scripting.

Scripting has been possible on the Macintosh since the release of the first version of Hypercard. Hypercard's scripting language of Hypercard is Hypertalk [Winkler Kamins and Devoto 1994]. With this scripting language it is possible to develop quite advanced Hypercard-based applications packages. However, Hypertalk is not the only scripting system for the Macintosh. More recently, Apple has developed Applescript as a general scripting language. Many applications for the Macintosh now support Applescript scripting capability. Apple subsequently extended the concept of scripting with the introduction of Apple Events — a message that can be sent to an application to tell it to do something [Trinco 1995]. From Version 2.2 onwards, Hypercard has supported Applescript as well as Hypertalk. Hypercard therefore has the capability of both to act both as a system integration tool as well as a user interface construction tool.

Scripting can also be accomplished in a number of other ways. Scripts can be attached directly to Hypercard objects such as buttons and check boxes. Using this approach, the user interface would be designed in Hypercard and Hypercard may also be used to provide other functions. Scripts can also be written and debugged in Script Editor, a scripting tool which is now supplied with every new Macintosh. Script Editor can be used to create standalone script applications but these lack an interface. To provide an interface another interface design tool is needed. Apple has been supplying the third-party package, Facespan, for this purpose. A third option is to use the Frontier scripting environment. Frontier was one of the first application development environments to take advantage of Apple Events. Frontier has its own scripting system which employs a hierarchical command structure. However, Frontier can also call Applescripts. Frontier has a user interface design tool called MacBird as well as a faceless relational database. However, Frontier's sophistication is a disadvantage as well as an advantage for it demands considerable skill on the part of the user.

In this project, it was decided to use Hypercard as the developmental environment. There were several reasons for this. Applications that are programmed in Hypercard can easily be modified easily. Hypercard therefore offers a very suitable environment in which to develop prototypes. Second, Hypercard player is standard with every Macintosh and therefore Hypercard applications can readily be moved between machines. Third, Hypercard offers quite sophisticated database capabilities which may be used in this project to generate a database of students' details. Lastly, and perhaps most importantly, Hypercard is presently being updated to a multimedia authoring environment making it even more suitable for the type of application being developed here.

Developing the prototype system

At the time of writing, the project has reached the stage of integration of the major components of the capture system.

Choosing a Macintosh platform simplified the task of physically connecting the various components. The Macintosh's support for the S-Video standard allows S-Video cabling to be used throughout minimising losses in quality of the video signal during transfers. The major task in bringing together the various components therefore involves the development of the control software.

The first task to be tackled was control of the video recorder. This was chosen because it was perceived to be the design goal that would be most difficult to attain. The recorder is designed to interface with a DOS/WINDOWS computer and differences between communication standards between the DOS/WINDOWS and Macintosh environments were expected to give rise to problems. Indeed, this was found to be the case. Problems were encountered with both the hardware and software. The hardware problems were solved by treating the recorder as though it were a modem. The software problems proved to be more difficult.

Hypercard lacks the capability of controlling the modem port directly. To communicate with the modem port from Hypercard therefore requires additional software. The first approach that was used was to add Apple's System Tools extension to the system and an XCMD called CommConnect to Hypercard. This provided the communications link that was needed. However, all attempts to transmit commands from Hypercard to the recorder failed. An alternative approach was therefore tried. This was to use an Applescript applet. This worked flawlessly.

Mailing of messages will be accomplished by using Eudora. Eudora is highly scriptable and all functions of the package that will be required for this project, including compilation of the text message and attachment of the video clip, will be able to be controlled from Hypercard.

Development of the student database is being undertaken in Hypercard itself. Student information will be stored in a Hypercard stack and individual student's details will be accessed by selecting from a scrolling list. Selecting a student's name will indicate to the system whether or not the student has e-mail access and, if so, the student's current e-mail address.

Contrary to initial expectations, the most difficult aspect of the project is turning out to be controlling the process of video capture. While Apple has developed an XCMD for replaying Quicktime movies, no-one appears to have developed an XCMD for capturing movies. The approach that is being used is therefore once again to use scripting to control another application. However, few capture packages offer scripting control. FusionRecorder, which is no longer a current product, offers some scripting capability and it is hoped that this will prove suitable.

Limitations of the prototype system

The most important limitations of the prototype system relate to data handling. As has been explained, the capacity constraints of e-mail hosts feeds through to other aspects of the system's design and places tight constraints on the best that can be achieved at the present time. In the prototype, every avenue of reducing the amount of data that is generated is resorted to — the frame size, frame rate, the number of colours in which the image is captured and the duration of the video clip are reduced to a minimum. This has an obvious effect on the quality of the resulting image. Obtaining an improvement in the quality of the image therefore depends on improvements in technology. However, it is safe to assume that such improvements will be forthcoming.

The choice of Hypercard as the development environment may be considered by some to impose limitations on the speed of operation of the system. However, the penalty here is slight and the advantages that Hypercard offers far outweigh the disadvantages.

The fact that the prototype will only be able to support one-way transmission of video is a major limitation of this implementation of the video e-mail concept. However, it is not such a major limitation in the context in which the pilot is being developed. Again, improvements in technology will overcome this limitation.

Possible future developments

In describing the way in which we have managed to combine a variety of technologies, I would not like to leave the impression that the system we are developing promises to put video e-mail in the hands of every distance educator. The system is very much experimental. It has many shortcomings in its present form, not the least of which is the quality of the images we can transmit. It is in fact a testbed for trialling the concept. However, all the factors that we have identified as limiting the performance of the system are likely to become less problematic as technology improves. The value of the project to us has been the opportunity it has given us to get to grips with the many complexities of video capture, video compression, mailing of non-text attachments, and scripting. This knowledge can now be extended to a number of other applications.

Although the way in which we have assembled the components of the system is specifically designed to support video e-mail, the general approach being used in this project can readily be adapted to use in conjunction with a bulletin board. In this case, video clips would be posted to the bulletin board rather than being e-mailed directly to the student. This approach would be particularly applicable to bulletin boards maintained on the World Wide Web. Posting video clips on bulletin boards could offer educational advantages in many situations because this would enable students' work to be made available to other students to view. This is a concept which we intend to develop alongside the video e-mail system.

Conclusion

The project that has been described in this presentation has both technological and educational components. The early phase of the project has, of necessity, had to be focussed more on technological than on educational issues. To someone who is more concerned with educational issues, the problems that have had to be tackled may seem too technical to be of interest to educational specialists. Yet it is the way technical problems such as those that have been encountered here are tackled that determines the range of possibilities that we have available to us in education. Perhaps the greatest lesson that has been learnt from this project so far is that the lessons learnt from this project are likely to be applied in a variety of directions. That, surely, is what innovation is all about.

Three Important Research Agendas for Educational Multimedia: Learning, Children, and Gender

Kori Inkpen
Department of Computer Science
The University of British Columbia
Vancouver, British Columbia, V6T 1Z4, Canada
inkpen@cs.ubc.ca

Abstract: This paper discusses three often-overlooked characteristics of educational multimedia systems that are important for human-computer interaction (HCI) researchers: (a) learning environments have very different goals and approaches than do workplace environments, so HCI research must investigate issues within the context of learning; (b) what works for adults will not necessarily work for children, so HCI research must develop usability guidelines that are appropriate for children; (c) girls and boys interact differently with technology, so HCI research must understand how each gender interacts with computers. We illustrate each of these issues with examples from our own research and explain how the characteristics of educational multimedia systems can lead to computing environments that do not hinder children's learning and do not exclude any children on the basis of gender.

Keywords: Human-Computer Interaction (HCI), children, learning, education, gender, educational multimedia, interaction styles, games, collaboration

Introduction

Human-Computer Interaction (HCI) research has primarily been concerned with adult users in the workplace. When investigating HCI issues for the design of educational multimedia for children, it is important to look beyond the existing body of HCI research and re-examine specific issues in the context of learning environments, the needs of children as users, and issues of gender.

The thrust of HCI research is that users should not have to adapt to the technology, but instead, the technology should be designed to support the needs of the users. Historically, computer users have been adults in the workplace, while today users can be any age and encompass many groups within society: male and females, young and old, and all cultural and economic groups, just to name a few. As the definition of user grows, HCI research is also expanding to encompass the wide variety of users interacting with technology. In order to fully understand the needs of these new users, we must also understand the context and the environment in which the systems will be used. It is because of this that new areas within HCI are developing such as Computer-Support for Collaborative Learning Environments (CSCL).

This paper presents three important research agendas for HCI. First, we must recognize that learning environments have very different goals and approaches than do workplace environments, and it is important to investigate issues within the context of learning. Secondly, it is important to look at the differences between adults and children in the context of computers. What works for adults will not necessarily work for children. Finally, it is important that we understand how each gender interacts with computers so as to not exclude any children.

While educational multimedia can be used by a wide variety of people in numerous settings, this paper will focus on educational multimedia for children in a school environment. This paper will present past and present research as well as directions for the future to help in the development of educational multimedia.

Learning: Workplace vs. Learning Environments

One of the primary goals for using computers in the workplace is to help improve workers productivity while learning is commonly a secondary goal. In contrast, learning is one of the primary goals for the use of computers in an educational environment. This, in itself, will cause users to view and interact with systems differently.

Usability Guidelines for the Workplace and Learning Environments

Researchers in HCI have developed a set of usability guidelines, and design and testing techniques to help improve the design of products for the workplace [Anderson & Olson 85]. Use of these guidelines for the design of educational multimedia products for children, while perhaps is useful, does not acknowledge the fact that learning environments are often different from workplace environments. [Robertson 94] has suggested that traditional usability design guidelines and usability testing methods need to be revamped for educational software.

Productivity vs. Entertainment

One of the most striking differences between individuals in the workplace and children in school is their motivation for using technology. At work, the motivation to use computers comes from the need to complete the task components of a job. While children also use computers to complete a task assigned by the teacher, the real motivation that children have to interact with technology is *enjoyment*. For computers to be effective for adults in the workplace, computers must be easy to use and help the individuals complete their day-to-day tasks. For computers to be effective for children at school, they must be fun. Several researchers have noted the potential benefit of educational software if it facilitates the children's motivation to play as observed when they play electronic games [Klawe 92, Soloway 91].

Collaborating on Multiple Networked Machines vs. a Shared Machine

One example of the difference between designing for the workplace versus the classroom can be seen in the area of Computer-Supported Cooperative Work (CSCW). The premise for many CSCW systems is multiple people, *each with their own machine*, working together towards a common goal. Often, these machines are networked together to support the collaboration. This could be in the form of a meeting support system or a shared word processor. In contrast, in the classroom, where learning is the ultimate goal, often the verbal discussion of ideas and hypotheses is a key component of the learning process. This may be best facilitated when the children are sitting side-by-side, talking face-to-face, both focusing on the same artifact. Therefore, a good approach in designing a Computer-Supported Collaborative Learning (CSCL) tool for use in a single classroom may be to focus on children collaborating on the *same machine*, and deciding how to best support this type of collaboration. Researchers have begun to explore the concept of providing a shared screen with multiple input devices to enable multiple children to work together on the same computer [Inkpen et al. 97b, Inkpen et al. 95, Bricker et al. 95].

Children: Adults vs. Kids

The computers that children use at home and at school for the most part look like the machines that you can see on most desks in the business world. We have taken a product, developed for adults in the workplace, and given it to children for school and play. How do we know that this machine is designed appropriately for children? Most of the software on these computers had been adapted for children but this adaptation has, for the most part, been designed in an ad-hoc manner. Very little research has been conducted on how to effectively design computer software for children. With computers becoming more prevalent in the education system, it is critical that we understand how children interact with computers and the most effective way to design the hardware and software.

Motor Skill Development

Some researchers have noted that children have difficulty performing mouse operations that require sustained pressure on the mouse button [Inkpen et al. 97a, Inkpen et al. 96, Stromme 94]. [Inkpen et al. 97a, Inkpen et al. 96] investigated two common mouse interaction techniques for children: drag-and-drop and point-and-click. A preliminary study looked at girls playing two different versions of the same computer game, one which utilized a drag-and-drop interaction style while the other utilized a point-and-click interaction style [Inkpen et al. 96]. This study showed that girls were able to solve more puzzles using the point-and-click version of the game than using the drag-and-drop version. In addition, girls using the point-and-click version of the game were also more motivated to play. A follow-up study examined children moving objects around on a screen using either a drag-and-drop interaction style or a point-and-click interaction style [Inkpen et al. 97a]. The results of this study suggested that a point-and-click interaction style was better for children than the drag-and-drop interaction style, based on children's preference, speed, and number of errors committed.

Cognitive Differences

A few researchers have begun to notice that adults' computer interaction styles are not necessarily appropriate interaction styles for children. [Berkovitz 94] noted that children have a lot of difficulty stretching a selection rectangle around a group of objects. Children often misplaced the initial point of the selection rectangle and therefore missed some of the objects that they were trying to select. Error in placement of the initial point could be attributed to two causes: 1) the inability of children to understand where the initial point should be placed in order have the box to encompass all of the appropriate objects, or 2) a lack of planning on the part of the children before initiating the action. [Berkovitz 94] suggested a selection technique that was more appropriate for children where they could "push out the edges" of the selection rectangle. This improvement not only allowed for the traditional method of dragging the mouse along the diagonal of the rectangle, but also enabled the children to use a circular gesture to define the selection rectangle.

Experiential Differences

These examples show how children have physical or cognitive difficulty using adult interaction techniques commonly found in children's computer software. We also need to be concerned about how the children make sense of the applications they are using. One particular design strategy in HCI is to design products that encourage users to form the correct mental model of a system. This can be accomplished by having the application use metaphors for something that the user is already familiar with [Norman 83]. Because children have different experiences and perspectives than adults, common adult metaphors may not make sense to children. One common adult metaphor found in software is the desktop metaphor but, as [Jones 90] states, this is not an appropriate metaphor for children. Children do not have much experience in office environments with file folders and in-out trays. Instead, child-appropriate metaphors should be used. [Jones 90] suggests that the best way to achieve this is through user-centered design.

These results emphasize the need to continue exploring HCI issues for children. Children are not adults: their motor skills are not fully developed, their cognitive capabilities are different, and their motivation for using computers is different. If we carelessly develop educational multimedia tools we may jeopardize our children's ability to learn with the tools.

Gender: Girls vs. Boys

Girls and boys interact differently with computers. Girls and boys think about computers differently, have different motivations for using computers, approach computers differently, have different preferences, and have even shown differences in the ability to use various interaction styles [Hall & Cooper 91, Inkpen et al. 95, Inkpen et al. 97a, Inkpen et al. 97b, Upitis & Koch 96, Lockheed 85, Wilder et al. 85]. Because of this, when designing educational multimedia, we must be sensitive to gender issues to ensure that the products developed are appropriate for children of both genders.

Gender Stereotypes in Electronic Games

Earlier research on children interacting in an electronic games environment found several difference between girls and boys [Inkpen et al. 94, Lawry et al. 95]. The differences included the types of games the children liked, what aspects of the games were important to them, and to what degree the games were a part of their social environment. Unfortunately, many electronic games are designed by men, for the young male market. Gender prejudices can be found in many electronic games that involve violence and use women as "objects" to be rescued [Provenzo 92]. This in itself is a major problem because often, electronic games are often a gateway for children to become involved with computers [Papert 93]. Not only is it important to develop products that are appropriate for both genders, it is imperative that the products developed do not promote the negative stereotypes of either gender.

Complexity of Gender Differences

Research must be conducted in order to begin to understand the complex nature of gender differences. Previous research had shown that software designers incorporate their own gender biases into the software that they develop [Huff & Cooper 87]. Often, these gender biases will cause the designers to miss important subtle nuances with respect to gender differences. For example, a math prototype game was developed for girls and boys. When playing with a partner, two modes of play were available: *compete* mode and *team* mode. Before presenting this game to children, researchers assumed that girls would prefer to play in *team* mode and boys would prefer to play in *compete* mode. The game involved having a frog hop around on lily-pads according to a mathematical problem. In *compete* mode, each partner had their own frog and their own score. In *team* mode, there was only one frog and both partners contributed to a single score. When the prototype was presented to children, the developers realized that their intuitions were wrong. The girls preferred to play in the *compete* mode because they could each have their own frog. For girls, the sense of identity, and character was important. Boys, on the other hand, preferred to play in *team* mode because they recognized that if they worked together, they could get the highest score in the whole class! Even though the boys were competitive, they were willing to cooperate with one person in order to have a higher level of success and compete with the rest of the class. This example demonstrates that the gender differences exhibited in a computer environment can be complex and easily misunderstood without proper research.

Gender Differences in Collaborative Environments

Qualitative, anecdotal observations are useful but quantitative data may also be required to sort out gender differences. Quantitative data on children's collaborative behavior was collected in a study which involved children played a puzzle-solving game in various collaborative set-ups [Inkpen et al. 97b]. The collaborative protocols included pairs of children playing the game with either one *shared* mouse or two mice. In the two-mouse conditions, two protocols were used to transfer control between the mice: *give* and *take*. In the two-mouse *give* condition, the partner in control of the game cursor would press their mouse button to pass control of the game cursor over to the other partner's mouse. In the two-mouse *take* condition, either partner could take control of the game cursor by pressing their right mouse button at any time.

The results from this study revealed that girls solved more puzzles in the two-mouse *give* condition than in either of the other two conditions. While the number of puzzles that boys solved in the various conditions was not statistically different, further analysis of boys sharing patterns revealed that boys exhibited quite different behavior in the three conditions. In the two-mouse *take* condition, boys demonstrated a more equal distribution of mouse time between the two partners than in the other two conditions. In addition, a correlation was found between how long each boy had control of the mouse during a collaborative session and how well they could perform later on their own. If our goal is to have all children benefit from the collaborative session, then an equal distribution of mouse time would be advantageous.

It is important that we continue to explore how both girls and boys interact with computers and ensure that all of our HCI research is sensitive to gender issues.

Advancing the Agendas

The three research agendas presented here, namely, learning environments, children, and gender all converge into one common focus: user-centered design. In order to design effective educational multimedia we must understand how children of both genders interact in a learning environment.

The project group E-GEMS (Electronic Games for Education in Math and Science) at the University of British Columbia and Queen's University is employing user-centered, participatory, design as its main research approach. Prototype educational games are being developed and tested with students in four elementary school as key participants in the design [Klawe & Phillip 95]. The E-GEMS classrooms (three in Vancouver, British Columbia and one in Kingston, Ontario), have each been equipped with four Macintosh computers. The teachers and students in these classrooms test out the prototypes and give valuable feedback. The children's feedback involves not only what they like and don't like about the game but also suggested improvements or enhancements. Beyond designing and testing games, E-GEMS is also examining how to incorporate educational electronic games into the classroom and the curriculum.

E-GEMS researchers also spend a great deal of time in elementary schools either having children try out their ideas or conducting studies on old or new interaction styles [Inkpen et al. 95, Inkpen et al. 97b, Sedighian 96]. In addition to elementary schools, E-GEMS researchers conduct research at Science World BC, an interactive science museum in Vancouver, British Columbia. By constantly working with children, the E-GEMS researchers and designers are always putting the needs of children first, and are always trying to better understand these needs.

Research on how to effectively design and use educational multimedia in a learning environment, for girls and boys, has still only scratched the surface of the iceberg. Continued research is needed, with the emphasis on user-centered design. Merely creating educational software and placing it in front of children is not enough.

The Evolution Thematic Investigator: Research and the Design of Hypermedia Learning Environments

Michael J. Jacobson
Learning and Performance Support Laboratory
University of Georgia
United States of America
mjacobso@coe.uga.edu

Abstract: This paper describes the main design features of a case-based hypermedia learning environment, the *Evolution Thematic Investigator*, that was developed as part of a research project into learning complex biology knowledge at the high school level. This hypermedia program has a number of features based on recent cognitive learning theory and research, such as: conceptual change lesson, multiple cases of evolutionary biology, case-theme commentaries to make explicit the situated variability of the neo-Darwinian mental model, on-line scaffolded problem-solving modules, and guided thematic criss-crossing of knowledge synthesis study questions. Research into student learning associated with the use of the Evolution TI has found significant conceptual change from predominately naive Lamarckian models being used by students to solve evolutionary biology problems on the pretest to neo-Darwinian models on the posttest and again at a one year follow-up study. This paper focuses primarily on the design features of the Evolution TI as an exemplar of a case-based hypermedia learning environment.

It may be argued that traditional instructional approaches are not well-suited for helping students deeply learn centrally important but difficult to understand domain concepts and mental models (Brown, Collins, & Duguid 1989; Cognition and Technology Group at Vanderbilt 1990; Collins, Brown, & Newman 1987; Glaser 1991; Spiro, Feltovich, Jacobson, & Coulson 1992). However, merely providing access to technological learning systems such as powerful multimedia computers are unlikely to lead to substantive learning of knowledge (Jacobson, Maouri, Mishra, & Kolar 1995; Neuman, Marchionini, & Morrell 1995). Principled design approaches for hypermedia learning environments (HLE) are needed to inform both the design of the technology itself and the learning activities and conditions under which HLE can be used to help promote substantive learning [Jacobson 1994].

The HyperBio Project has been part of a program of research into issues such as these [Jacobson & Spiro 1994]. In particular, the HyperBio Project has investigated ways hypermedia can be designed and used to achieve three main goals: (a) acquisition of *deep understandings* of centrally important and difficult domain knowledge, (b) *conceptual change* of naive domain models, and (c) ability to *transfer* or *apply* knowledge to new situations. This paper will focus on HyperBio Project research into learning the neo-Darwinian theory of evolution by natural selection.

From a research perspective into learning with HLE, the domain of evolutionary biology is particularly interesting. Understanding neo-Darwinism is absolutely essential to contemporary biology [Dobzhansky 1973], yet the core concepts of evolution by natural selection are significantly more difficult for students to grasp than most biologists and science teachers imagine [Bishop & Anderson 1990]. Further, there is evidence that most students will need to go through a process of conceptual change from a naive "Lamarckian" model (i.e., traits acquired by the parents are passed on to the offspring) to the scientifically accepted neo-Darwinian model (i.e., evolution occurs by a process whereby organisms have traits that are differentially suited for surviving in specific environmental niches and thus living long enough to reproduce and pass on their genetic material--that is, they are naturally selected) [Bishop & Anderson 1990; Brumby 1984; Greene 1990; Jacobson, Sugimoto, & Archididou 1996; Settlage 1994]. As discussed below, specific features of the Evolution Thematic Investigator (TI) were designed to address the conceptual change issue. Our research into student learning associated with the use of the Evolution TI has found significant conceptual change from mainly naive Lamarckian models used by students to solve evolutionary biology problems on the pretest to predominately neo-Darwinian models on the posttest and at a one year follow-up study [Jacobson & Archodidou, in press; Jacobson et al. 1996].

This paper will focus primarily on the actual design features of the Evolution TI as an exemplar of a case-based hypermedia learning environment. In the next section, these various design features and learning activities are discussed.

Evolution Thematic Investigator

The Evolution TI has seven main components that were used in this study: (a) a *conceptual change lesson* on evolution, (b) *multiple cases* of evolutionary biology, (c) presentation of a *neo-Darwinian model of evolution with five core themes*, (d) *case-theme commentaries* to make themes of the neo-Darwinian model explicit in the context of different case examples, (e) *mental model visualizations* of both naive Lamarckian and expert neo-Darwinian evolutionary models, (f) *scaffolded problem-solving* with the interactive Story Maker modules, and (g) *guided thematic criss-crossing* with knowledge synthesis study questions. These seven major features of the Evolution TI are briefly discussed in turn.

Conceptual Change Evolution Lesson

As noted above, prior research has established that many students enter biology classes with a strongly entrenched naive Lamarckian mental model. A computer-based evolution conceptual change lesson was developed that implemented the basic recommendations of a conceptual change approach to science education: (a) create dissatisfaction with existing conceptions, (b) make a new conception intelligible, (c) make a new conception appear initially plausible, and (d) demonstrate how a new conception can open up additional areas of inquiry (Posner et al. 1982; Strike & Posner 1990). The evolution conceptual change lesson presented naive Lamarckian and neo-Darwinian mental model visualizations (see below), discussed the inadequacies of the naive model of evolution, and demonstrated how the neo-Darwinian model could successfully be used in place of the naive Lamarckian model.

The lesson initially asked the students to articulate their knowledge about evolutionary biology in two ways. First, they ran two evolution mental model visualizations, one representing a naive Lamarckian model and the other a neo-Darwinian model. They were then asked to select which one was closest to their understanding of how evolution occurred. The students also were asked to use the Story Maker (see below) to propose a solution to a classic evolutionary biology problem: How did giraffes evolve long necks?

The text of the Evolution and Natural Selection lesson was *not* written to convey to the students that they might have the "wrong" ideas about evolution and that the Evolution TI was going to teach them the "right" ideas about evolution. Rather, the lesson discussed the core ideas of two competing scientific views of evolution, Lamarckism (referred to in the lesson as the Developed Traits Scientific Story) and Darwinism (referred to as the Natural Selection Scientific Story; see [Tab. 1].

Multiple Cases of Evolutionary Biology

Four different hypermedia-based cases of evolutionary biology were developed: *The Peppered Moth*, *Antibiotics and Drug Resistance*, *Anglerfish*, and *Rabbits in Australia*. These cases illustrated central themes of neo-Darwinian evolutionary theory. In addition, these cases depicted evolutionary phenomena that were intended to be interesting, distinctive, and relevant. For example, the *Antibiotics and Drug Resistance* case discussed the relevance of neo-Darwinian evolution by natural selection to an important contemporary health issue. Another case, *Anglerfish*, dealt with a variety of fish that have a particularly distinctive anatomical feature: they have appendages in place of the top dorsal fin that are used as lures to "fish for other fish." The various cases of evolutionary biology illustrate the situated or contextual variability of knowledge while making salient the deep conceptual structure of this domain, that is, the neo-Darwinian model of evolution by natural selection.

Central Themes for Neo-Darwinian Model

The contemporary neo-Darwinian theory of evolutionary biology is quite elaborate and complex. The purpose of this study, however, was not to have students learn evolutionary biology at the level and depth of a professional biologist. Instead, this research focused on having students acquire a mental model based on core components or themes of neo-Darwinism. Five neo-Darwinian themes were selected for this study: (a) Environmental Conditions, (b) Population Variety, (c) Natural Selection, (d) Origin of New Traits, and (e) Generations and Time. [Tab. 1] lists the core components of each of these themes as they are instantiated in the neo-Darwinian and naive Lamarkian models. General theme descriptions were available from most portions in the program.

Case-Theme Commentaries

Case-theme commentaries made explicit how structural dimensions of knowledge (e.g., the neo-Darwinian themes) applied in various case-specific or situated contexts (Jacobson et al. 1995; Jacobson & Spiro 1995). The Evolution TI provided case-theme commentaries in which the neo-Darwinian themes were discussed in terms of specific details in the evolution cases. For example, the theme of Population Variety had a case-theme commentary in the Peppered Moth case that pointed out the variations in the wing colorations of these moths. In the case of Antibiotics and Drug Resistance, the Population Variety commentary discussed the variation in bacterial resistance to antibiotics.

Mental Model Visualizations

Newly available visualization technologies are allowing dramatic, animated, scientific images to represent complex scientific data (Gordin & Pea 1995). Scientific visualizations have been primarily used to provide representations of quantitative data for complex phenomena (e.g., weather data) and are typically based on expert scientific models about the phenomena under investigation. We have been developing another approach to using visualizations for learning that we call *mental model visualizations*. Our intent was to create computer-based visualizations that *reified mental models* held by learners and experts. In contrast to scientific visualizations, the mental model visualizations we have developed are qualitative in nature and are based on cognitive analysis of novice and expert mental representations about a particular domain. In terms of this specific study, the evolution mental model visualizations were intended to *make neo-Darwinian thinking visible* to students by providing computer animated representations about evolutionary biology to supplement the case, theme, and case-theme commentaries that were primarily textual. Four neo-Darwinian visualizations and one naive Lamarckian evolution mental model visualization were created (based partly on the research of Bishop & Anderson 1990).

Evolution Themes	**Neo-Darwinian Model**	**Naive Lamarckian Model**
Population Characteristics	Population *variety* essential for evolution through natural selection	Population *homogeneity*; small individual differences do not matter for evolution
Environmental Conditions	"Neutral" environment; varying & dynamically changing environmental conditions	Environment "creates" need that causes the organism to change
Mechanism of Inheritance	*Natural* selection; individuals with advantageous traits (genetically predetermined) more likely to survive and reproduce.	*Acquired traits*; traits partially developed by parents passed on to off-spring
Origin of New Traits	Random changes in genetic material: 1. Mutations 2. Sexual recombination	Species changes due to: 1. Environmental need 2. Use or disuse
Generation and Time	Evolutionary changes require cycling of generations; time scales vary from hours to thousands or millions of years	Acquired traits gradually change entire population over time

Table 1: Core components of naive "Lamarckian" and expert Neo-Darwinian evolutionary biology models

The evolution mental model visualizations were developed using MacroMedia Director 4.0. Five evolution mental model visualizations were created (e.g., naive Lamarckian for "Bugs" conceptual change example; neo-Darwinian for "Bugs" conceptual change example; neo-Darwinian mental model visualization for Peppered Moth case,). Each of these followed the same basic template in which the learner stepped through the mental model visualization with short informational text augmenting the graphics in four to eight different environmental situations selected by the learner. Other features of the evolution mental model visualizations included an Overview screen showing all of the branching options with thumb-nail figures, a Thumbnail summary of the generational changes on the left side of the screen, and a Case Information icon that provided an abstract of the particular example or case on the lower right side of the screen.

Other Program Features

There were two additional features of the Evolution TI: *scaffolded problem-solving* with the Story Maker and *guided thematic criss-crossing*. The Story Maker modules provided interactive, scaffolded problem-solving activities. Students were given evolutionary biology problems to solve, such as "How did giraffes get their long necks?" They would then select from a pool of randomly arranged statements consistent with naive Lamarckian and neo-Darwinian models on the left side of the screen. The statements they selected would each be changed to an italics style and then copied to the right side of the screen. Statements on the right side could be reordered or removed. When the students were satisfied with the statements they had selected, the program would evaluate the response and provide brief feedback about whether their answer was similar to the Lamarckian scientific view of evolution by acquired traits associated or to the now accepted neo-Darwinian view of evolution by natural selection.

The Evolution TI program also provided *guided thematic criss-crossing* (Guided TCC) in conjunction with *knowledge synthesis study questions* [Jacobson et al. 1996; Jacobson & Spiro 1995]. Knowledge synthesis questions asked the students to consider issues and problems that required the integration of information distributed across the hypermedia case materials they had been studying. Previous research suggests that students who are novices in a domain have difficulty with learning and integrating conceptual knowledge in hypermedia materials [Jacobson 1996; Neuman, Marchionini, and Morrell 1995]. Guided TCC provided cognitive scaffolding to demonstrate the conceptual interconnectedness of knowledge in the hypermedia cases through the use of different sets of hyperlinks based mainly on neo-Darwinian thematic indices. These different sets of hyperlinks were tailored to specific knowledge synthesis questions in a manner that has been found to contribute to learning for transfer in previous research [Jacobson 1996; Jacobson & Spiro 1995].

Conclusion

This paper has discussed the main design features of the Evolution Thematic Investigator case-based hypermedia learning environment and some of the learning activities which employed this system in a study of conceptual change and evolutionary biology. While these design elements have been instantiated here in the domain of evolutionary biology, other research by our group is suggestive of ways that case-based hypermedia learning environments with conceptual indexing can be created for other domains ranging from the social impact of technology and military strategy to bio-medicine [Jacobson, Maouri, Mishra, & Kolar 1996; Jacobson & Spiro 1995; Spiro, Feltovich, Jacobson, & Coulson 1992]. Other research is being planned that seeks to explore ways that newly available visualization, modeling, and immersive technologies might be integrated into case-based learning environments in a cognitively and pedagocically principled manner [Jacobson 1996]. Elaborating on those ideas, however, is a story for another day.

Abstract: Modern computer technology allows precise coordination of text and graphic information and may provide learners with tools for enhancing acquisition of abstract and complex programming knowledge. This study explored the hypothesis that an electronic learning environment with appropriate graphic representations can facilitate abstract knowledge acquisition when students learn recursive procedures. In this study, college students were taught to learn the Scheme programming language and the concept of recursion in the three learning conditions: on-line Scheme recursive procedures, in which dynamic visual notations (e.g., colored icons and environment trees) accompanied to progressively represent intermediate steps of each procedure's run-time state; on-line Scheme recursive procedures, in which an ordered sequence of static pictures accompanied to explicate each procedure's run-time process; on-line Scheme recursive procedures with merely textual explanation. Results of this study indicate that limited textual information with rich and appropriate animated or static graphic representations can provide students a better framework for understanding the concept of recursion.

Key words: Language learning, Visual thinking, Mental model building

Introduction

The ancient proverb, "a picture is worth a thousand words", has already characterized the efficiency of external visual representations for communicating ideas. Visualization strategies of learning and problem solving have provided a good number of historical accounts of scientific discovery and invention [Ferguson, 1977; Rieber, 1995]. For example, mathematicians have made extensive use of diagrams to solve geometric problems. Scientists in the domain of physics and chemistry also have utilized a vast amount of diagrammatic information to analyze and interpret data. Research has indicated that textual information with appropriate adjunct visual aids can enhance reading comprehension [Bransford & Johnson, 1972; Sharp, Bransford, Goldman, Risko, Kinzer, Vye, 1995]. Even though visual information is not available, readers still try to utilize visualization strategies to form mental imagery to comprehend texts [Anderson & Kulhavy, 1972]. Thus, visualization strategies for learning and problem solving pervade all people.

Some investigators have contended that the form of human mental representation is purely propositional [Pylyshyn, 1973], while others considered that the form of internal propositional representation is different from that of visual imagery, and people are able to encode information in these two different forms [Paivio, 1990]. Although the controversy about distinguishability of these two types of mental representation can not immediately be resolved, different forms of external representation indeed affect human cognition differently. Even for textual information, relevant research has indicated that when two texts that are informationally equivalent but represent things with different propositional forms may cause people construct different situation models to represent what is described in the text [Kintsch, 1986; Perrig & Kintsch, 1985]. For example, people read a text describing a city in geographic terms (e.g. The general store is on the southern end of the Main street) will represent information about locations differently from people who read a text describing routes and places of that city (e.g. Returning on the Main street to the other end, you come to the general store). Studies have also indicated that the acquisition of spatial knowledge through two different representational forms can cause people mentally represent information differently [Thorndyke & Hayes-Roth, 1982]. For the instructional purpose, it is important to know whether certain knowledge should be represented with pictorial information so that learners can acquire and comprehend that knowledge more efficiently than would be the case that the knowledge is represented with textual information.

Visual representations are different from textual information in that visual representations mainly consist of spatial (i.e. typological and geometric relations among the objects or events), nonarbitrary (i.e., the quality of visual information resembling actual objects and events), and continuous (i.e., an "all-in-oneness" quality) characteristics [Larkin & Simon, 1987; Paivio, 1990; Rieber, 1995]. Text-based representations are arbitrary and sequential (e.g., readers usually read a text based on its semantic sequence instead of randomly scanning a picture of it), and may reflect temporal and logical relations among external events. In addition to preserving characteristics of visual information, dynamic visual representations or an ordered sequence of static visual representations are able to represent temporal and causal relationships between states [Freyd, 1987].

Most programming languages lack properties to explicitly demonstrate intermediate steps of a running program. This makes it difficult for beginners to learn to write computer programs. For example, the run-time phenomenon of a recursive procedure usually is not visible and also difficult to describe with merely textual information. As a result, learning the concept of recursion becomes a major hurdle for most novice learners. Since dynamic visual representations or an ordered sequence of static visual representations are able to capture characteristics of most objects or events, they are best suited to explicitly represent complex programming concepts, such as recursion, and may assist students to learn.

The development and increased availability of the multimedia technology allows objects and events to be represented with dynamic or static visual forms. Several multimedia instructional systems with a dynamic visual display of knowledge have been developed for math and science instructions. Some of them have been proved to be effective [Dugdale, 1994; Klotz, 1991; Jehng, Liang, Shih, & Chan, 1994]. The use of multimedia with dynamic or static visual representations has its instructional advantages for learners to acquire abstract knowledge. First, a multimedia learning environment with appropriate visual information could provide more visual cues (e.g. colors, icons, flash light and reverse video) to illustrate certain significant and important aspects of abstract knowledge. Second, a multimedia learning environment with appropriate external visual displays of knowledge may reduce learners' cognitive load during learning, more memory capacity can be released so that conscious processing can be devoted to higher-level cognitive operations as necessary. Finally, a multimedia learning environment with visual representations usually can characterize different aspects of knowledge and make knowledge more explorable. Students are more likely to construct their own mental models to understand that knowledge and work toward more encompassing explanations.

This study attempted to investigate whether students who just begin to study the concept of recursion and learn to trace execution steps of recursive procedures in a multimedia learning environment with either dynamic or static visual support would learn the concept and the programming skill effectively and demonstrate a superior problem solving ability than those who learned in a multimedia learning environment with only textual information provided. The concept of recursion is complex and abstract, and many programming languages fail to explicitly illustrate the execution steps of recursive procedures at the run-time so that learning recursion could be difficult for novice learners. The multimedia learning environment provides either dynamic or static visual representations can be an efficient approach to capture and teach the deep structure of the concept of recursion and make it easier to learn. Results of this study should provide us an understanding of how a multimedia learning environment with appropriate visual representations can help teach and learn complex programming knowledge.

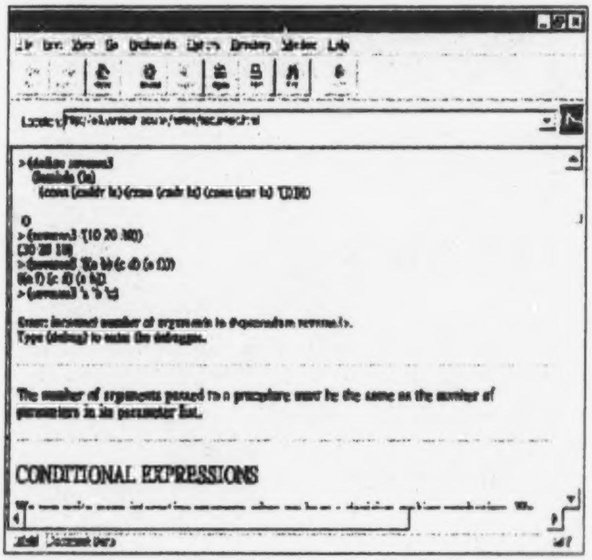
Methods

Participants Subjects in this study were 38 senior students from the Department of Management Information Systems at the National Yunlin Institute of Technology, Taiwan. They participated in this study for fulfilling requirements and earning credits on a programming language course. All of them, having learned to program in a few introductory computer science courses, did not learn the Scheme programming language before and had minimum knowledge about the concept of recursion.

Materials and Design Subjects were randomly assigned into the three conditions to learn the concept of recursion. At the initial lecture session, subjects in each group were introduced the

Scheme language and the concept of recursion using an on-line text without any ancillary visual representations. They were, then, asked to review what they had learned in three different conditions. The review materials designed in the three conditions were informationally equivalent with different presentation formats. In the control condition, 12 subjects would review the same on-line text without any visual aids. Thirteen subjects in the first experimental condition would read an on-line text with an ordered sequence of static graphic information accompanied to illustrate the execution process of recursive procedures. For the control and the first experimental condition, the learning materials were compiled into HTML files and presented in the WWW environment where students reviewed the materials using the Nescape 3.0 application. In the second experimental condition, 13 students would review what they had learned with the RainbowScheme system, which allows the evaluation steps of a Scheme recursive procedures to be presented step by step in an algebra form. This learning environment used high-level visual objects, such as colored Scheme expressions, clickable icons, and colored environment trees, to represent each Scheme recursive procedure's run-time state. The visual information provided in the two experimental conditions applied one or more *Visualcode* rules. *Visualcode* is a graphical representation of Scheme's operational semantics [Tung, 1996].

Procedure A randomized block design model was used that the students' achievement in computer programming related courses was regarded as control variable. Students were randomly assigned into three groups. Subjects in each group first received a two-hour lecture from the instructor about the Scheme language and its simple recursive procedures from an on-line text. The material was projected and presented on a big screen inside a classroom with an overhead projector connected to a computer. Subjects were then asked to review what they had learned from the lecture in three different conditions. The first group of subjects were assigned into the control condition where subjects were arranged to review the material with the same on-line text as in the lecture session. Subjects in the second group would study an on-line text with an ordered sequence of static pictures accompanied to demonstrate the execution process of recursive procedures. The third group of students would review the lecture material by working with the RainbowScheme system, that allows students to study the text with dynamic pictorial representations. Figure 1, 2, and 3 show the computer screens of the three learning conditions. All subjects took two hours to review the instructional materials individually. After the experiment, they were requested to take a test on recursion.



The number of arguments passed to a procedure must be the same as the number of parameters in its parameter list.

Figure 2. Static pictorial representations of recursive procedures

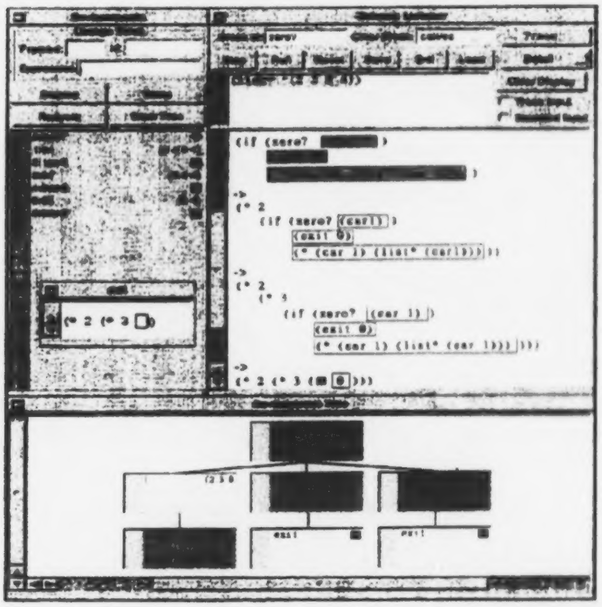

Figure 3. Dynamic pictorial representations of recursive procedures in RainbowScheme learning environment

Post test materials The post-test measure contains 12 problems: three of which were *evaluation* problems requiring students to evaluate Scheme recursive procedures by predicting results; another three of which were *diagnosis* problems requiring students to diagnose faulty Scheme recursive procedures and make corrections of them; another three were *fill-in-blank* problems requiring students to finish incomplete Scheme recursive procedures; the final three were *programming* problems requiring students to define and complete Scheme recursive procedures on their own. Evaluation and diagnosis problems mainly examined students' capabilities of tracing and evaluating recursive procedures; fill-in-blank and programming problems examined students capabilities of defining and completing recursive procedures. The post-test lasted one hour and forty minutes.

Data Analysis and Results

Student's scores on the evaluation and diagnosis tests were combined to represent their program evaluation skills, and their programming skills were measured by the fill-in-blank and programming tests. An ANOVA analysis of student overall performance in the post-test showed that students who studied in both experimental groups significantly outperformed those who studied in the control condition with F = 4.196 ($p < .05$). The average scores of student overall performance in the static pictures, dynamic pictures and control group are 7.42, 6.79, and 4.86 in sequence. The result of the Duncan's priori pairwise comparison analysis indicated that students' overall understanding of Scheme recursive procedures is enhanced with the aid of external visual representations. Specifically, analyses of student performance on the post-test measure showed that the three groups of students demonstrated different programming skills, but not the program evaluation skills. Subjects in the two experimental groups significantly outperformed those who studied in the control group in the programming skill test with F = 4.277 ($p < .05$). The average scores of student performance in programming skill test for the static pictures, dynamic pictures and control group are 3.29, 3.19, and 1.83 in sequence. The result of the Duncan's priori pairwise comparison analysis indicated that visual aids can help students improve their programming skills, but not the program evaluation skills. Although statistics did not show any significant differences in student performance on the program evaluation test, subjects in the two experimental groups still had higher mean scores than those who in the control group. Table 1 shows that results of the analysis.

Table 1. Student performance on the post-test measure.

	Static-pictures (N=13)	Dynamic-pictures (N=13)	Control (N=12)	F-test	Prob.
Evaluation skill	4.13(1.15)*	3.60(1.31)	3.03(1.43)	2.236	.1219
Programming skill	3.29(1.36)	3.19(1.49)	1.83(1.29)	4.277	.0218
Overall	7.42(1.98)	6.79(2.45)	4.86(2.41)	4.196	.0232

* indicates mean score with standard deviation in parenthesis.

Closing Commentary

Results of this study support the claim that textual information with appropriate ancillary dynamic or an ordered sequence of static visual representations can assist students to learn to trace recursive procedures and understand the concept of recursion efficiently. Students demonstrated superior problem solving skills in diagnosing, tracing and defining recursive procedures after they had learned the concept of recursion in a condition where dynamic and an ordered sequence of static pictorial representations simulated the computer behavior demonstrating the execution process of recursive procedures. Dynamic and an ordered sequence of static pictorial representations showed qualitatively different effects on students' intellectual performance and capabilities. Such an usage of computer technology may expedite the acquisition of the knowledge that students are always required to learn.

The reason that account for the significant effect of dynamic and an ordered sequence of static pictorial representations on learning of recursion could vary. First, dynamic and an ordered sequence of pictorial representations are capable of explicitly displaying intermediate steps of the execution process of recursive procedures; this allowed students to analyze a recursive procedure's run-time state easily and quickly identify its concept structure. The step-by-step demonstration facilitates students to build their own mental models to precisely interpret what they were learning from the screen. Whereas, the textual information is not able to demonstrate the run-time state of a recursive procedure in transition. It is more difficult for students to construct their own understanding by making sense of what they were reading from the screen. An alternative account is that dynamic and an ordered sequence of static pictorial representations can reduce students' cognitive load and free students from lower level and tedious cognitive operations that exceed their cognitive capacities during learning. Psychological research has indicated that people has a tendency to form a dynamic mental representation and make accurate inference of a moving objects from an ordered sequence of static display [Frayd, 1983; 1987]. With the aid of dynamic or an ordered sequence of static pictorial display, students do not need to conduct much conscious processes to mentally simulate computer execution of recursive procedures. It is easier for novice learners at the initial stage of learning readily comprehend a complex and abstract concept of recursion and accurately interpret the execution process of a recursive procedure without expending much mental efforts. Meanwhile, dynamic or an ordered sequence of static visual representations allow students to perceive execution process of recursive procedures in real time changes. Students do not have to take much intellectual effort as those students in the textual information conditions to infer, analyze, and predict intermediate steps of program execution. More working memory capacity can be released for higher level cognitive operations so that in-depth processing of knowledge is possible.

Finally, dynamic and an ordered sequence of static pictorial representations are capable of representing different aspects of the concept of recursion and make the knowledge more explorable than the form of textual representations. The form of dynamic and an ordered sequence of static pictorial information is capable of representing the temporal features of execution processes of recursion and logical relationships between transitions so that students can readily see how a recursive procedure is being executed and can mentally simulate that process. Students can perceive and compare different kinds of recursive procedure's run-time phenomena represented by the two types of visual information. For example, students can perceive and compare the execution processes between tail and non-tail recursive procedures and accurately relate differences of their execution processes to the program structures. The concept of recursion become more explorable and analyzable.

The notion that computer can be used for cognitive tools for enhancing learning has been proposed by many educational researchers [Pea, 1985; Salomon, 1988; Salomon, Perkins, & Globerson, 1991]. The research discussed in this paper suggests that a multimedia learning environment that provides appropriate dynamic or an ordered sequence of static pictorial representations can be used for facilitating acquisition of complex and abstract programming knowledge. Student can envision what they have learned and their novel thoughts can be extended to more powerful problem solving ideas through visualization strategies. Future research should explore more effective visualization techniques with computers for teaching and learning abstract and complex knowledge.

MacSQEAL: A Tool for Exploration of Hypermedia Log File Sequences

Tricia Jones, School of Education (triciaj@umich.edu)
Matthew Jones, Department of Electrical Engineering & Computer Science (mjones@eecs.umich.edu)
University of Michigan, Ann Arbor, MI

Abstract: In this paper, we present an exploratory technique for investigating student interaction with hypermedia. We describe a tool for exploratory sequential analysis of the transformed data and present examples of how this tool has been used to analyze a large collection of log files. We describe our data source to provide context for analyzing the data, discuss an innovative way to investigate sequences in log files, and provide examples of results obtained from our method.

1 Previous Work: Methods for Log File Analysis

Researchers examining how students use hypermedia software systems often analyze the student interaction with the software as recorded in a database [Ambrose 91]. These data are commonly referred to as "event recordings" or "log files," for they contain a log or record of choices or events within the software. There are several advantages to automated event recordings, as described by [Guzdial et al. 96]:

- Data collection is completely unobtrusive.
- Data are collected during actual use in an authentic context, which improves the ecological validity of the study.
- Data can be easily collected for a large sample of students over time.
- Data can be compared between students or over time for a single student.

Automated event recordings yield a vast amount of high fidelity data [Jackson 90]. This high volume challenges researchers trying to make sense of the data, and attempting "to make useful conclusions from essentially intention-free data" [Guzdial et al. 96, p 2].

One of the goals of log file analysis is to identify prominent patterns of use [e.g. Horney 93; Hutchings et al. 94] and correlate those with other quantitative measures such as ACT scores [Beasley & Vila 92]; however, many such studies are weak in interpreting these results and the implications for design or learning. These techniques suffer from a lack of specific detail: why did these students use a certain feature and ignore another? what are the students' goals, objectives, motivations, strategies? [Jones et al. 96] suggest that a combination of log files and interview data could be used to address such questions. The analysis of interviews could suggest hypotheses about student use; and these hypotheses could be checked against the larger data set.

Numerous techniques have been explored for making sense of log files. [Chen et al. 95] reviews existing techniques. [Guzdial et al. 96] contrasts methods used by a different research groups, applied to a single hypermedia system. According to Guzdial et al., there are two types of questions to investigate with log files: (1) determine aggregate measures used to characterize a given student or session (e.g. how many times did they look at a particular media type? how often were articulation actions followed by reflection?), and (2) examine the sequences of actions taken by a given student. In reference to sequences, the two techniques discussed by Guzdial et al. are measures of differences and similarities, and visualizations of event orderings. Similarity matrices are used to characterize the overall process used by a student – e.g. 30% of the time they went from A to B, but 10% they went from A to C – and identify groups of similar students (by applying multi-dimensional scaling or cluster analysis to the similarity matrix). Visualizations provide imprecise, but intuitive insight into sequence patterns that emerge when sequences are mapped into graphics. [Jackson 90] describes a very different technique for examining sequences, by applying sequence comparison methods from biology and geology.

Unfortunately, these techniques are not scalable or tolerant of the wide variation in event patterns characteristic of our data. We needed a speedy and flexible tool to perform ad-hoc sequence queries based upon hypotheses formed from interview data.

This paper extends [Jones et al. 96] by showing how hypotheses generated from interviews can be tested in the larger sample. We will describe our data source to provide context for the analytic method, discuss an innovative way to investigate sequences in log files, provide examples of results obtained from our method, and conclude with implications and future work.

2 Data Source

2.1 Context

The research reported here is part of a larger study examining the use of *Seeing Through Chemistry* in the context of the introductory chemistry course at a large midwestern research university. The design of the larger study is naturalistic. We used a variety of data collection techniques – scores, surveys, interviews, etc. – and a combination of micro- and macro-level data analysis from both quantitative and qualitative perspectives to examine the impact of *Seeing Through Chemistry*.

Seeing Through Chemistry (STC) is a multi-faceted hypermedia learning environment designed to facilitate students' development of conceptual understanding in introductory chemistry [Dershimer & Rasmussen 90]. STC's design applies psychological principles of learning and human-computer interaction [Dershimer et al. 92]; in particular, cognitive flexibility theory [Spiro et al. 88]. The six modules within STC correspond to key topics in the first-semester course. Within these modules, students must synthesize several concepts in order to answer each of a series of inquiry question. The inquiry questions have two parts: a multiple-choice component and an explanation; students must type an explanation before they can check the accuracy of their choice.

Throughout the term, students were required to answer the inquiry questions for five of the six modules in *STC* and turn in the printed version of their responses (the printout shows their initial and final response to each question). During the student assignments, *STC* automatically captured the sequence and duration of choices made by the student. Furthermore, it recorded all answers and revisions typed in response to inquiry questions. This information was captured to log files, one per student, so that each log file records completely a student's use of *STC* throughout the semester.

2.2 Characteristics of the Data

200 of the 450 students enrolled in this multi-section large lecture course agreed to participate in the study; we have log files for each participating student. In addition, we selected a stratified random sample of 12 students (based on background in math & science, and experience with technology) for more intensive participation. This target group participated in stimulated recall interviews for two modules, based on the trail map representation of their log file. These interviews played a significant role in the current analysis.

[Tab. 1] displays some characteristics of the modules in *Seeing Through Chemistry* and how students in this sample used the modules. Overall, there were 121,390 distinct events logged for this sample of students.

Module	Unique Events	N	total events per student	range	unique events	total time (min)
Spectroscopy	100	198	μ=175	25-455	54.5	78.7
ReDox	70	194	μ=113	32–315	38.2	48.7
Properties & Structures	102	195	μ=145	12–374	25.4	55.6
Acids & Bases	58	191	μ=95	26–289	13.9	39
Solubility & Precipitation	52	182	μ=95	13–253	14.3	39.9

Table 1: Characteristics of Student Use of *Seeing Through Chemistry*

We have identified potentially important characteristics of student use through interview analysis and log file visualizations. However, it is not practical to extend such an in-depth investigation to a sample of 200 students. To that end, we created a set of tools for processing the log files and performing ad-hoc queries on sequences. The queries we form are grounded in an awareness of the behavior of the target group.

3 Our Technique

Our tool is called MacSQEAL (which stands for Macintosh-based Sequence Query Engine for Analyzing Logs). It is built using the cross-platform programming language Perl [Wall 89], and achieves its flexibility by making extensive use of Perl's pattern matching capabilities.

We use three steps to transform our log files into sequences appropriate for MacSQEAL:

- convert events into more abstract representations
- recode for selective distinctions

- segment into sequences

MacSQEAL searches the transformed data for sequence patterns. The researcher specifies sequence patterns using extended regular expressions, as defined by the Perl programming language. MacSQEAL also provides a number of functions that restrict searches to specific modules, questions, or other selection criteria.

To date, we have used the tool primarily in two different ways: to extract aggregate data (e.g. how many students use a question–card–response pattern for Question 2 in the Acids & Bases module?) and form more complex queries (e.g. of those students who demonstrated a question–response pattern for Question 2 in Acids & Bases, which ones also exhibited this pattern for Question 4?).

3.1 Data Transformation

Step 1: Event Conversions/Abstraction. Abstraction is necessary when a log file contains a large number of relatively uncommon events. For example, a module in STC contains roughly 50 to 110 distinct events [Tab. 1], that correspond to a much smaller set of types: concept map (m), content card (c), inquiry question (q), response (r), animation (a), video clip (v), experiment (e), focus question (f).

Step 2: Selective Distinction. Some kinds of analysis require more precise discriminations between events than the abstraction step provides. For example, for any given inquiry question in *STC* there are "relevant" cards (they appear on a list of topics that should be contained in the ideal answer). When examining how students construct their explanations for the inquiry questions, we are interested in whether or not they examined "relevant" cards; as a result, we recode the sequences to distinguish between "relevant" (uppercase C) and other content cards (lowercase c).
